Preface

Document conventions

The document conventions describe text formatting conventions, command syntax conventions, and important notice formats used in Ivanti technical documentation.

Text formatting conventions

Text formatting conventions such as boldface, italic, or Courier font may be used in the flow of the text to highlight specific words or phrases.

Format	Description
bold text	Identifies command names
	Identifies keywords and operands
	Identifies the names of user-manipulated GUI elements
	Identifies text to enter at the GUI
<i>italic text</i>	Identifies emphasis
	Identifies variables
	Identifies document titles
Courier Font	Identifies command output
	Identifies command syntax examples

Command syntax conventions

Bold and italic text identify command syntax components. Delimiters and operators define groupings of parameters and their logical relationships.

Convention	Description
bold text	Identifies command names, keywords, and command options.

Convention	Description
<i>italic text</i>	Identifies a variable.
[]	Syntax components displayed within square brackets are optional. Default responses to system prompts are enclosed in square brackets.
{ x y z }	A choice of required parameters is enclosed in curly brackets separated by vertical bars. You must select one of the options.
x y	A vertical bar separates mutually exclusive elements.
< >	Non-printing characters, for example, passwords, are enclosed in angle brackets.
...	Repeat the previous element, for example, member[member...].
\	Indicates a “soft” line break in command examples. If a backslash separates two lines of a command input, enter the entire command at the prompt without the backslash.
bold text	Identifies command names, keywords, and command options.

Notes and Warnings

Note, Attention, and Caution statements might be used in this document.

A Note provides a tip, guidance, or advice, emphasizes important information, or provides a reference to related information.

Attention: An Attention statement indicates a stronger note, for example, to alert you when traffic might be interrupted or the device might reboot.

Caution: A Caution statement alerts you to situations that can be potentially hazardous to you or cause damage to hardware, firmware, software, or data.

Requesting Technical Support

Technical product support is available through the Ivanti Global Support Center. If you have a support contract, file a ticket with Ivanti Global Support Center.

- Product warranties—For product warranty information, visit <https://forums.ivanti.com/s/contactsupport>

Self-Help Online Tools and Resources

For quick and easy problem resolution, Ivanti provides an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <https://forums.ivanti.com/s/contactsupport>
- Search for known bugs: <https://forums.ivanti.com/s/contactsupport>
- Find product documentation: <https://www.ivanti.com/support/product-documentation>
- Download the latest versions of software and review release notes: <https://forums.ivanti.com/s/contactsupport>
- Open a case online in the CSC Case Management tool: <https://forums.ivanti.com/s/contactsupport>
- To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://forums.ivanti.com/s/contactsupport>

For important product notices, technical articles, and to ask advice:

- Search the Ivanti Knowledge Center for technical bulletins and security advisories: https://forums.ivanti.com/s/searchallcontent?language=en_US#t=KNOWLEDGE%20BASE&sort=relevancy
- Ask questions and find solutions at the Ivanti Community online forum: <https://forums.ivanti.com/>

Opening a Case with Ivanti Global Support Center

You can open a case with Ivanti Global Support Center on the Web or by telephone.

- Use the Case Management tool in the Ivanti Global Support Center at <https://forums.ivanti.com/s/contactsupport..>

For international or direct-dial options in countries without toll-free numbers, see <https://forums.ivanti.com/s/contactsupport>

Reporting Documentation Issues

To report any errors or inaccuracies in Ivanti technical documentation, or to make suggestions for future improvement, contact Ivanti Technical Support (<https://forums.ivanti.com/s/contactsupport>). Include a full description of your issue or suggestion and the document(s) to which it relates.

Revision History

Release	Update
22.7R1.5	Removed IF-MAP support. For more information, see KB article .
22.7R1	Added support for "Using IPv6" on page 1086 and "Security Hardening" on page 1106
22.6R1	Updated the optional and Mandatory fields in Configuring Host Checker Policy
22.6R1	Updated the optional and Mandatory fields in Configuring Host Checker Policy
22.6R1	Updated the Configuring Auth Table Mapping Policies in Configuring IPS with FortiGate Firewall , "Deployment of IPS using SRX Firewall" on page 327 "Deployment of IPS using PAN Firewall" on page 277 and "Deployment of IPS using Check Point Next-Generation Firewall" on page 262
22.6R1	Updated Allowing Required IP Addresses and Using the Authentication Report

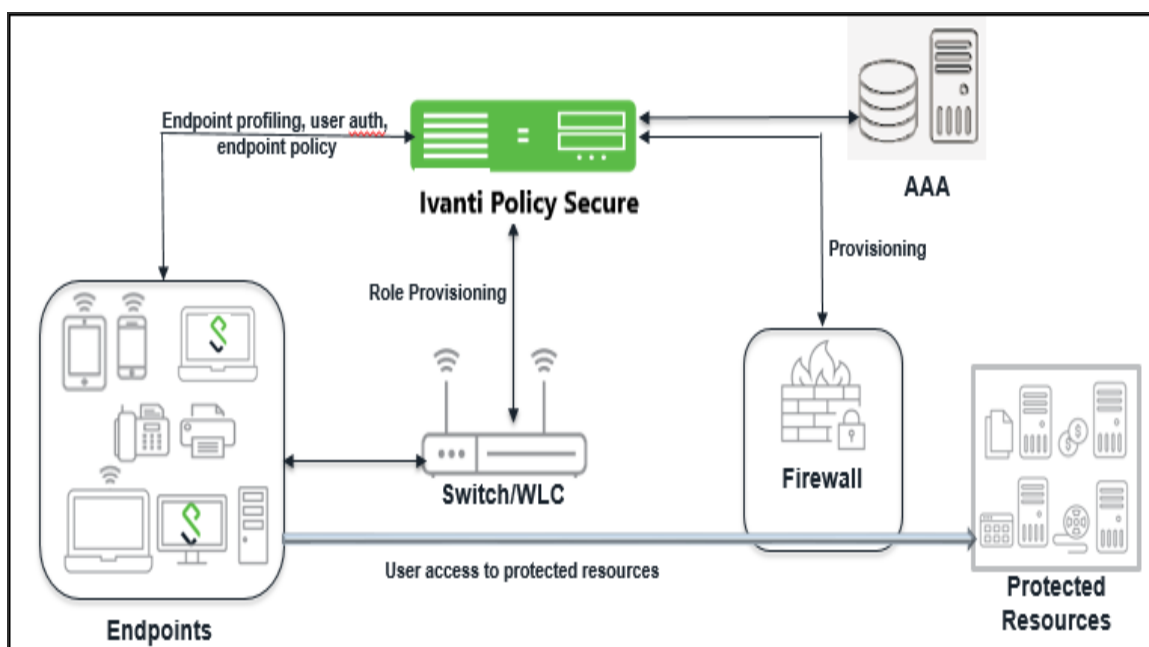

Introduction to Ivanti Policy Secure

Overview

Ivanti Policy Secure (IPS) is a network access control (NAC) solution which provides network access only to authorized and secured users and devices. It protects your network and guards mission critical applications and sensitive data through comprehensive NAC management, visibility, and monitoring.

It reduces the cost and complexity of delivering and deploying granular, identity, and role enabled access control from the branch to the corporate data center. It also addresses most NAC challenges, which includes insider threats, guest access control, and regulatory compliance.

The IPS solution leverages AAA framework, which contains the user profiles, attributes, group roles and identities. It then binds the user identity information to the endpoint and to the network and uses the resultant policy to map the user to the appropriate role during the access session.

IPS solution uses endpoint validation to place the users into specific access groups. The groups can be provisioned access to different resources based on access control mechanisms such as virtual LANs (VLAN), filters, or access control lists (ACL). You can also define additional QoS parameters for the session for role based policy enforcement so that only authorized users can access the application and data. The solution allows access only from users who are compliant with the security policies that you define. IPS also works well with unmanaged devices, such as printers, VoIP phones, and IP enabled cameras. You can configure typical hosts, such as VoIP phone, that is not 801.1X enabled to be permitted to the network using SNMP enforcement and the Profiler. The integration with Profiler enables IPS to build a database of the unmanaged devices on the network and have the same access security as managed devices. IPS solution is extremely flexible and offers numerous options for integration into your existing network. When an endpoint connects to the network, IPS gathers user authentication data, endpoint security state data, and device location. It combines the information to create dynamic policies or uses the user created policies, which are then propagated to enforcement points. The enforcement can be either at the edge of the network prior to granting an IP address using 802.1X, within the network on the firewall, or both for greater granularity.

IPS Components

IPS solution consists of the following main components:

- Ivanti Policy Secure (IPS)—A central policy management server that validates the user's identity, determines the endpoint's security compliance, and manages network policies.
- Enforcer—Policy enforcement points for user authentication. For example, switches, firewall, and WLCs.
- Ivanti Secure Access Client—Client running on endpoints for user authentication, device compliance using IPS.
- Profiler—It dynamically identifies and classifies endpoints across managed and unmanaged endpoint devices, so that access to network and resources can be controlled based on the type of the device.

IPS offers the following benefits:

- Centralized management of Access and Compliance policies.
- Easy integration with several Authentication, Authorization, and Accounting (AAA) servers.
- Role-based, application-level enforcement.

- Allows context-aware policy enforcement for wired and wireless connections across desktop and mobile platforms.
- Distributed enforcement of network access policies.
- Dynamic endpoint assessment and enforcement.
- Supports compliance based network access for endpoints.
- Supports comprehensive network visibility with simplified auditing, and monitoring of devices.
- Supports interoperability with existing network infrastructure such as switches, wireless controllers, AD, firewalls, IDS, and Security Information and Event Management (SIEM).
- Extends policy enforcement with information from Enterprise Mobility Management (EMM) solutions. IPS supports leading global-device management solutions from MobileIron, AirWatch, and Microsoft Intune. IPS works with the Mobile Device Management (MDM) solution to evaluate whether the BYOD or corporate devices are compliant with organizational and MDM policies.
- Supports automated device onboarding, self-service enrollment, and integration with existing infrastructure to simplify deployments.
- Supports Simple Network Management Protocol (SNMP) in the network device definition for the Profiling service to communicate with the network devices and profile endpoints that are connected to the network devices.
- Delivers guest user access control capabilities for simple, seamless, and authorized network access to guests.
- Supports captive portal capabilities for allowing users onto their guest networks and capturing relevant information

IPS Enforcement Modes

To provision resource access policies, you can use 802.1X Layer 2 switch, access point, or firewall within any enterprise class network edge infrastructure that supports 802.1X and Remote Authentication Dial-In User Service (RADIUS).

The following types of devices can be used as IPS enforcement points:

- Infranet Enforcer (Firewall) —Devices that control traffic flow based on Layer 3 data. You can use Palo Alto, Check Point, Fortinet, Juniper Networks SRX series and Screen OS firewalls as enforcers. For more information, see Layer 3 Enforcement.
- 802.1X devices—You can use any 802.1X enabled switches or access points with IPS. The 802.1X protocol provides port based authenticated access to LAN. This standard applies to both wireless and wired networks. For more information, see Layer 2 Enforcement.

You can use 802.1X enabled switches or access points with or without the Infranet Enforcer as part of the solution. If you do not deploy the Enforcer, the 802.1X enabled switch or access point functions as the enforcement point. You can create different security zones by configuring VLANs on the network and assigning different roles to the appropriate VLAN.

Allowing Required IP Addresses

The IPS uses a series of IP addresses and ports to facilitate access to the admin and user web consoles, for user enrollment, and for connections to Ivanti Policy Secure. To ensure network access, make sure the following IP addresses and ports are added to the allowed list in your network firewalls and routing infrastructure.

If IPS devices are connected to NSA and nZTA controllers. For detailed information refer to [KB24280](#).

The following table lists the NSA Azure IP instance ranges and n ZTA tenant IP range. Select the IP addresses and ports for your corresponding region only.

Region	External IPs	External IPs
North America	52.186.44.249 (port 443)	52.188.33.186 (port 443)
Europe	51.138.111.17 (port 443)	20.50.150.82 (port 443)
APJ	20.44.238.229 (port 443)	20.44.237.67 (port 443)
UAE	20.233.40.108 (port 443)	20.233.41.69 (port 443)
Canada	20.220.157.85 (port 443)	20.220.157.158 (port 443)

Licensing

Introduction

Ivanti Policy Secure is a licensed software and the licenses can be downloaded from Software Download Center @ <https://my.pulsesecure.net>. The licenses can be applied directly on the IPS or can be leased from the License Server.

Alternatively, you can install and manage licenses directly on each device and eliminate the license server entirely. Your company's needs and requirements dictate which configuration is best for you.

Significant Changes 22.2R1 Release

- User Core License are introduced for ISA devices. Concurrent user will reset to two users, if core license is not installed or leased.
- 22.1R1 and later release supports License server and can lease license to 22.x and 9.x clients.

Significant Changes in IPS 22.x Release from IPS 9.x Release

The following list shows the significant changes in IPS 22.x compared to IPS 9.x:

- Introduction of IPS SKUs
- Does not support PSA-specific concurrent user licenses
- Core licenses and V-FED are not required for upgrading and creating clusters
- Supports existing Feature licenses, excluding the deprecated features (see the section Features not Supported)
- Install licenses directly on the Standalone IPS Gateway.
- GW Licensing mode
- IPS 22.x supports the following platforms:

ISA Model Name	vCPUs	Memory	Max Concurrent Users
ISA4000-V	4	8GB	500
ISA6000-V	8	16GB	10,000
ISA8000-V	12	32GB	50,000 for VMware

End User License Agreement (EULA) acceptance is mandatory, and you are entitled to use the features of the software that you have licensed within the limits of your Proof of Entitlement. Contact your sales representative for more information.

Gateway Licensing

The IPS Gateway supports new IPS SKU's. The following table lists the few sample IPS SKUs:

SKU	Example
IPS Perpetual	IPS-ADD-1000U
IPS Subscription	IPS-SVC-GLD-2000U-1YR IPS-SVC-PLN-1000U-1YR IPS-PAR-GLD-1000U-1YR IPS-PAR-PLN-1000U-1YR
Eval License	IPS-EVAL-2W
ICE License	ISA4K-ICE-GLD-1YR ISA6K-ICE-GLD-1YR ISA4K-ICE-PLN-1YR ISA6K-ICE-PLN-1YR

Obtaining and Installing License Keys

You can install licenses directly on the IPS Gateway by obtaining authentication code via email and then download and install licenses.

- [Installing licenses on a Standalone Gateway](#)
- [Configuring the IPS VM as a License Client](#)
- [Configuring License Server](#)

Installing License on a Standalone Gateway

An admin obtains an authentication code for his entitlement externally via e-mail.

To obtain license keys:

- 1. Go to **System > Configuration > Download Licenses**.
- 2. Under **On demand license downloads**, enter the authentication code in the text box.
- 3. Click on **Download and Install**.
- 4. Now, go to the **License Summary** tab to view a list of licenses installed.

▼ Licensed capacity

Maximum Concurrent Users: 2

Feature	Effective	Leased
Concurrent Users for ISA	2	0

A license server has not been configured. Please configure a [license server](#).

▼ Installed license details

Note that entering your license key signifies that you have read and agree to the terms described in the [license agreement](#).

License key(s):

Add

localhost2 - (0 users)

Machine ID: VASPHO70IB7WMUERE

Licensed to VASPHO70IB7WMUERE

- 5. To delete one or more licenses, select the corresponding check box(es) and click **Delete**.

Configuring IPS VM as a License Client

You can configure an IPS VM as a license client. As a prerequisite, you need ICS 9.1R13.1 License Server and above releases. You can also use 21.x and above releases for leasing licenses to clients.

To configure an IPS VM as a license client:

1. In the admin console of the license server, choose **System > Configuration > Licensing > Configure Clients**.
2. Click **New Client**.
3. Enter the Client ID. The ID is defined on the client Gateway under **System > Configuration > Licensing > Configure Server**.

Configure Clients >

Configure a new client

Enter or modify client settings on this page. Use the license allocation section to allocate more licenses to this client. The license allocation section will be modified based upon the platform selected for this client.

▼ License client settings

Lease Client Id: Identifier unique to this client

Password: Password unique to this client

Confirm Password:

Expiration date: / / Date until which the licenses in this configuration are valid. This field is optional

Platform: Platform type of this client

Product:

Virtual Platform: Available cores: 5000

▼ License allocation

Feature Name	Reserved Count	Incremental Count	Maximum Count	Leased Count
Concurrent Users for ISA	Available: 399900 <input type="text" value="0"/>	<input type="text" value="0"/>	<input type="text" value="0"/>	<input type="text" value="0"/>

4. Enter the client password and confirm it. The password is defined on the client Gateway under **System > Configuration > Licensing > Configure Server**.
5. (optional) Enter the client configuration **Expiration date**.
6. Select the client's platform as **ISA Virtual Platform**.

7. Select the product type to be configured to **Policy Secure**.
8. Select the **Virtual Platform** from the drop-down list for configuring ,example ISA4000-V
9. For each feature you want to lease to this client, enter:
 - **Reserved Count**— the number of licenses to reserve for this client. The reserve count must be less than the available amount displayed.
 - **Incremental Count**— the incremental number of licenses to grant when the client requests more licenses. If the number of licenses on the client plus this incremental value is greater than the maximum count, no additional licenses are granted.
 - **Maximum Count**— the maximum number of licenses a client can receive for this feature. This value must be equal to or greater than the reserved count. Available counts are updated as you configure the client.
10. Click **Save Changes**.

The License clients table displays the client information you entered.

Configuring a License Server

This section describes the steps to install and lease cores to license clients from license server.

1. Navigate to **System > Configuration > License Summary** page and install SKU on license server. Installing SKUs will also enable license server functionality on ISA License Server. No separate license server license is needed.

The following figure depicts the concurrent user on License Server before leasing Cores. You see that concurrent user is reset to two users, if core license is not installed or leased.

Profiler

Overview

Profiler dynamically identifies and classifies endpoints across managed and unmanaged endpoint devices, so that access to network and resources can be controlled based on the type of the device. It also helps you to get visibility and enforce your security policies for corporate access, BYOD, and guest access.

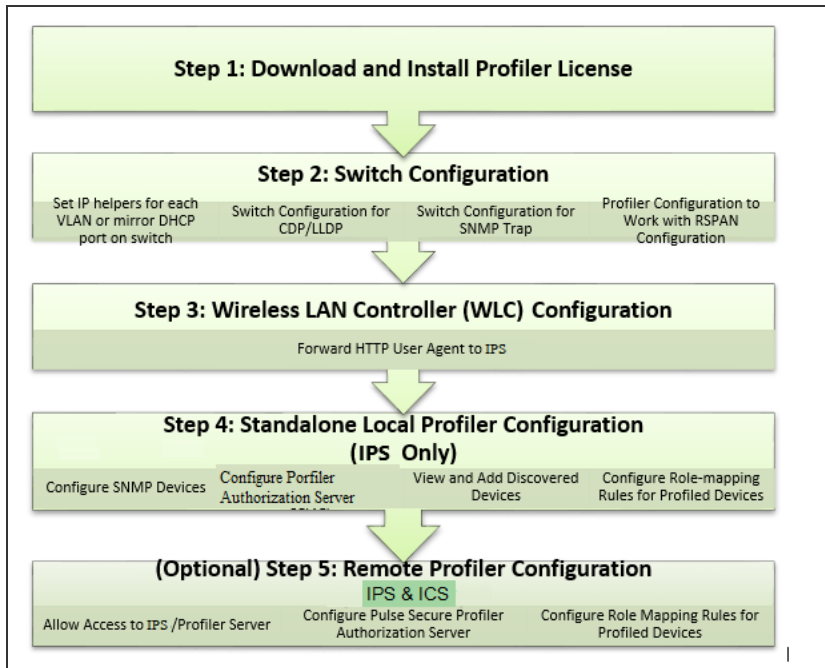

When you provision the authentication table from IPS to the firewall, ensure that the Profiler is configured with the Profiler Name and upload the FPDB, or do not configure the Profiler. If the Profiler is configured without uploading the FPDB, then the authentication table is not sent from IPS to Firewall.

The authentication table

The Profiler has the capability to:

- Detect and classify devices using DHCP fingerprinting.
- Provide access control for devices based on the device profile - mainly characterized by Manufacturer, Operating System, and Device Category.
- Provide visibility into IP-enabled devices connecting to the network.
- Enable MAC Authentication.
- Enable granular policies based on device attributes.

A high-level overview of the configuration steps needed to set up and run Profiler is shown in the following figure.

For more information on deployment and configuration, see [Profiler Deployment Guide](#).

Roles, Realms and Sign-In Policy

Overview

IPS access management framework allows only qualified users to access protected resources. The policies are created to allow or deny access to resources based on user's role and user's endpoint device compliance. The access management framework comprises of the following key elements:

User Roles

User role is used to categorize a group of users and accordingly provide access to a set of protected resources for these group of users. User role defines the type of access and the permissions required for accessing a protected resource. Administrator can define multiple user roles for the end users.

For example:

- Employees- Users who require access to all the company resources.
- Contractors- Users who work on a contract basis and require access to selected network resources.
- Guests- Users who visit the company and require limited access to network resources.

Authentication Realm

Authentication realm specifies the conditions that users must meet to sign-in to the system. A realm contains details about the authentication server with which the user is authenticated and list of restrictions/checks that needs to be passed on the client machine.

It also includes mapping of different users to different groups or roles with the use of role mapping rules.

- **Authentication Server**- An authentication server is a database that stores user credentials (username, password, group, and attribute information). The user logs-in to IPS through a specific authentication realm, which is associated with an authentication server, IPS forwards the user's credentials to the authentication server to verify the user's identity through AAA framework.

The IPS supports the following authentication servers:

- Active Directory
 - RADIUS
 - LDAP
 - RSA ACE/Server
 - Certificate
 - SAML Server
 - Mac Address Authentication
 - Local Authentication Server. For more information, see [Local Authentication Server Overview](#).
- **Authentication Policy**- It is a set of rules and restrictions to control resource access.
 - **Role-Mapping**- It consists of conditions a user must meet for IPS to map the user to one or more user roles. These conditions can be based on either the username, certificate, user information returned by the realm's directory server, or other administrator defined criteria.

The high-level configuration workflow is as follows:

1. Configure the Authentication Server
2. Configure User Roles
3. Configure Restrictions
4. Configure Authentication Realm
5. Configure Sign-in Policy

Sign-in Policy

Sign-in policies define the URLs that users and administrators use to access the device and connect to the network. This also provides option to the administrator to select the set of pages that users see during the sign-in process. Note that, these pages can be customized by using Custom Sign-in Pages option.

For example, if the enterprise has both PC users and mobile users, the admin can define two different URLs so that different authentication methods can be used. The ICS could log in to the IPS with an RSA token and their AD username and password. The mobile device use a client certificate (provided by an MDM solution) and the AD username and password.

User Roles

The user can be assigned to one or more roles during the sign-in process. A role is an entity which defines user session settings, role restrictions, appearance of the welcome page, and type of access methods (Ivanti Secure Access Client or agentless).

Creating Roles

To create a user role:

1. Select **Users > User Roles**. For creating Administrator role, select **Administrators > Admin Role**.

An administrator role specifies system management functions and session properties for administrators who map to the role. You can customize an administrator role by selecting the feature sets and user roles that members of the administrator role can view and manage.

2. Click **New Role** and then enter a name and, optionally, a description. This name is displayed in the list of Roles on the Roles page.

3. Under Options, specify the session and appearance details.
- **Session Options**—Sets timeouts and user permissions that apply to each session established through the role.
 - **UI Options**—Sets the appearance of agentless log in pages.
 - **Guest User Account Management**—Provides limited permissions to allow users assigned to this role to create guest accounts

User Roles > New Role

Configuring User Access Options

IPS supports connection through an agent (software) installed on the client device. The supported agent type is Ivanti Secure Access Client. The Administrator can configure what agent to install on the client device and the corresponding settings to push during the installation.

To configure the user access options:

1. Select **Users > User Roles > Role Name > Agent**.

User Roles > Users > Agent > General

General

General Agent Agentless

General Odyssey Settings

▼ Options

☒ Install Agent for this role

☐ Install Odyssey

☒ Install Pulse Secure client

☐ Enable Host Enforcer

Note:(Odyssey Access Client only) By default, if you enable Host Enforcer on a role, all traffic is blocked for users mapped to this role.
Make sure you create Host Enforcer policies on the "Resource Policies>Host Enforcer" page to allow particular traffic for this role.

Windows: Session start script
This script is executed after the session has started.

Script Location:

Windows: Session end script
This script is executed after the session has ended.

Script Location:

Save Changes

2. To allow Ivanti to download automatically on Windows endpoints, select Install Agent for this role, and then select the Install **Ivanti secure Access** option.
3. Under **Session Scripts**, specify scripts to run on Windows endpoints for users assigned to a role. For example, you can specify a script that maps network drives on an endpoint as a session start script, and you can specify another script that disconnects the mapped network drives as session end script.

Customizing UI Options

IPS provides options to administrators in customizing the page that gets displayed to the end users during sign-in process. These customization options are applied based on the list of user roles that are getting assigned to the end user. Using these options, administrators can change the logo, background and the welcome message that gets displayed to the end users during the sign-in process.

To customize the welcome page:

1. Select **Users > User Roles > Role Name > General > UI Options**.

The screenshot shows the 'UI Options' configuration page for a specific user role. The page is divided into several sections with expandable/collapsible headers:

- Header:**
 - Current appearance:** Displays the Pulse Secure logo.
 - Logo image:** Includes a 'Browse' button and a note: 'No file chosen. Less than 40 pixels tall and 150px.' Below this is a 'Background color' field with the value '#993333' and a color palette icon. A note says: 'Less than 40 pixels tall and 150px. (Selected from palette or type hexadecimal RGB)'.
- User Toolbar:**
 - Determine the tools that are available to users at the top of the page on the Pulse Policy Secure:** Includes a 'Show notification message' checkbox.
 - Personalized greeting:** Includes a 'Show notification message on user's welcome page' checkbox. Below it is a text area for the message.
- Informative:**
 - Show instruction message:** Includes a checkbox and a text area for the message.
- User Admin:**
 - Show User Admin instruction message:** Includes a checkbox and a text area for the message.
- Other:**
 - Show copyright notice and "Secured by Pulse Secure" label in footers:** Includes a checkbox.

At the top of the page, there are tabs for 'General', 'Agent', and 'Agentless', and a sub-tab for 'UI Options'. There are also buttons for 'Save Changes' and 'Restore Factory Defaults'.

2. (Optional) **Under Header**, specify a custom logo and alternate background color for the header area of the welcome page:
 - Click **Browse** and locate your custom image file. The new logo is displayed in the **Current appearance** box only after you save your changes.
 - Type the hexadecimal number for the background color, or click the Color Palette icon and select a color. The Current appearance box updates immediately.

3. Under **User Toolbar**, select the Session Counter check box to display both a session countdown timer and an Extend button that allows agentless users to extend their session time to the maximum session length if the Enable Session Extension option is selected.
4. (Optional) Under **Post-Auth Sign-In Notification**, select a post authentication message that you configured earlier. If you select this option, the user receives an information page (for example, an end-user license agreement [EULA]) that you have created.
5. (Optional) Under **Personalized greeting**, select the Show notification message check box, and enter a message in the associated text box. The message is displayed as a header on the welcome page after the user is authenticated. You can format text and add links using the following HTML tags: `<i>`, ``, `
`, ``, and `<a href>`. This information does not appear on the initial sign-in page that is displayed prior to authentication. You can also use system variables and attributes in this field. The length of the personalized greeting cannot exceed 12K, (12288 characters). If you use unsupported HTML tags in your custom message, the system might display the user's home page incorrectly.
6. (Optional) Under **Informative**, select the Show instruction message check box and specify any instructions to appear on the welcome page. For example, you could advise users of company privacy notices or usage restrictions, or you can link to another site for more information.
7. If you include a link to an external website, a warning message appears informing the user of loss of access privileges if they leave the current page. To avoid this, add a tag for opening links in a new browser window.

For example: `Google` displays the linked text "Google," and the link opens in a new browser window.

The instruction message supports non-English languages.

8. (Optional) Under **User Admin**, select the Show User Admin instruction message checkbox and specify any instructions to appear on the user admin page. Select Enable bulk user creation to create bulk user accounts for numerous users.
9. (Optional) Under **Other**, specify whether to display the copyright notice and label in the footer. This setting applies only to users whose license permits disabling the copyright notice. For more information about this feature, call Ivanti Support.
10. (Optional) Click **Restore Factory Defaults** to reset all user-interface options back to factory defaults.

11. Click **Save Changes**.

-
- If a user maps to more than one role, then the system displays the user interface settings that correspond to the first role to which the user is mapped.
 - Sign-in pages can also be customized using the Custom Sign-In page functionality. For more information, see [Configuring Custom Sign-In Pages](#)
-

Customizing the Session Options

IPS provides option to administrators for configuring the maximum session length and heartbeat interval for the end user sessions. Using these options Administrator can control how long the user sessions are allowed and the interval within which server should receive heartbeat from client device.

IPS also provides option to enable session roaming so that mobile users can continue to have the connection with server while roaming.

To specify general session options:

1. Select **Users > User Roles > RoleName > General > Session Options**.

Session Options

General Agent Agentless

Overview Restrictions **Session Options** UI Options

Save Changes

▼ **Session lifetime**

*Max. Session Length: minutes (min: 6)

*Heartbeat Interval: seconds (15 - 1800 seconds) Recommend greater than Host Checker interval (if enabled)

*Heartbeat Timeout: seconds

*Auth Table Timeout: seconds (60 - 86400 seconds) Auth table idle timeout value when auth table entry is provision as needed.

*Reminder Time: minutes (min: 3)

☐ Use Session/Idle timeout values sent by the primary RADIUS authentication Server

☐ Enable Session Extension Allow User to Extend Existing Session

☐ Allow VPN Through Firewall Allow Enforcer traffic to act as a Heartbeat and keep the session alive (Auth Table entries must be dynamic). Useful for endpoints that can authenticate but not maintain a heartbeat, such as non-multi-tasking endpoints, or when a VPN tunnel is established to a private network. NOTE: due to performance considerations, this feature only applies to new sessions.

▼ **Enable session timeout warning**

☐ Enabled

☒ Disabled

▼ **Roaming session**

Roaming sessions allow user sessions to work across source IP addresses. This is useful for mobile users with dynamically assigned IP addresses, as it allows them to sign in from their desk and continue working from a conference room.

☒ Enabled (maximize mobility)

☐ Limit to subnet (some mobility, increased security)

☐ Disabled (maximize security)

Save Changes

2. For **Max. Session Length**, specify the number of minutes an active non-administrative user session can remain open before ending. The minimum is 6 minutes. The maximum is 725 minutes. During a user session, prior to the expiration of the maximum session length, the system prompts the user to reenter authentication credentials, thereby avoiding the unexpected termination of the user session.

3. For **Heartbeat Interval**, set the frequency at which the endpoint sends out a heartbeat to IPS to keep the session alive. For agentless access, the browser refreshes the page with every heartbeat. Users must not the browser, because this will interrupt the heartbeat and end the session. Ivanti Secure Access Client and the Java agent provide the heartbeat. You should ensure that the heartbeat interval of the agent is greater than the Host Checker interval. If it is not, performance could be affected. In general, set the heartbeat interval to 50% more than the Host Checker interval.
4. For Heartbeat Timeout, specify the amount of time the system should “wait” before terminating a session when the endpoint does not send a heartbeat response.
5. For Auth Table Timeout, enter a timeout value for the auth table entry to be provisioned as needed. This parameter allows you to specify how long a user with no activity (for example, a user reading a static web page), can remain in the auth table before the auth table entry is cleared by the Infranet Enforcer.
6. Enter the reminder time in minutes.
7. Guest users (users created by guest user account managers) can log in with their guest account, and then tunnel into their corporate Virtual Private Network (VPN). In this case, the heartbeat connection to IPS is lost, and the user is disconnected after the heartbeat timeout expires. To prevent this, use firewall traffic as the heartbeat by selecting the **Allow VPN Through Firewall** check box.

When the “Disable use of **Allow VPN Through Firewall** check box is not checked (the default setting), AJAX requests are sent to the IPS at the configured interval. If the Use Traffic as Heartbeats option is enabled, AJAX heartbeat errors are masked.

If a guest user is assigned two roles, and one of the roles has a Host Checker policy and one doesn't, the user loses the role with the Host Checker policy if the Host Checker policy expires while the user is accessing a VPN through a tunnel. The user will lose access to the resources associated with the Host Checker role.

8. For agentless users, you can select the **Enable Session Extension** check box to allow users with a Layer 2 or Layer 3 connection to continue a session beyond the maximum session length.

If this feature is enabled, users with agentless access can be reauthenticated and extend their current session without interruption.

When the user session nears the end of maximum session length, a pop up a new sign-in page for agentless. When the user enters credentials, Host Checker verifies that the user is still compliant and the session continues.

When the user extends the session before its expiration, the session time is restored to the original maximum session length time that you have specified for the role, and the log indicates the new session time. If the user fails to extend the session before session time expires, the session is terminated.

For agentless access, you must select the Session Counter option on the UI Options tab to enable the session timer.

9. Under Enable Session timeout warning, specify:
 - **Enabled**-To enable expiration warning for users using Ivanti Secure Access Client.
 - **Disabled**-To disable expiration warning message.

10. Under Roaming session, specify:

- **Enabled**-To enable roaming user sessions for users mapped to this role. A roaming user session works across source IP addresses, which allows mobile users (laptop users) with dynamic IP addresses to sign in from one location and continue working from another. Disable this feature to prevent users from accessing a previously established session from a new source IP address. This prevents the spoofing attack on the user's session.
- **Limit to subnet**-To limit the roaming session to the local subnet specified in the Netmask box. Users may sign in from one IP address and continue using their sessions with another IP address if the new IP address is within the same subnet.
- **Disabled**-To disable roaming user sessions for users mapped to this role. Users who sign in from one IP address may not continue an active session from another IP address. User sessions are tied to the initial source IP address.

You must enable roaming for roles that are created for security policies that classify sessions into VLANs, for example, VLANs that have been provisioned for Users or Remediation. A session stores the client IP address. If the session gets placed in a different VLAN transition, the control channel is re-established, and a new IP address is sent to the server. If the remediation role does not have roaming enabled, the server terminates the session. This can lead to repeated problems. When the session is terminated, it causes a new log on, which reconnects to the same session, resulting in the same roaming problem. The Ivanti Secure Access Client sets a connection roaming error and logs the server FATAL_ERROR message.

11. Click **Save Changes**.

Configuring Role Restrictions

The role restrictions allow only a valid user to access the network and prevents unauthorized access. You can specify security requirements based on source IP address, password, certificate, browser type, and Host Checker policies. If the user does not meet the requirements specified in the restriction, then the user is not allowed to access the protected resource.

Source IP Access Restriction

Use a source IP restriction at the role to control from which IP addresses users can access a sign-in page. You must specify one or more IP addresses otherwise; no IP address restriction applies.

To enable Source IP access restriction:

1. Select **Users > User Roles > Select Role > General > Restrictions > Source IP**.
2. Assign the Source IP restrictions on roles.
 - **Allow users to sign-in** from any IP address- You can allow or deny access to any IP address/netmask combination. For example, you can deny access to all users on a wireless network (10.64.4.100), or you can allow access to all other network users (0.0.0.0).
 - **Allow or deny users from following IP address**- Enter the IPv4/IPv6 address, network/prefix length and choose whether to allow or deny access. Click **Add**.
3. Click **Save Changes**.

Certificate Access Restriction

Certificate access restriction restricts access only to clients that have a client-side certificates. You can further restrict access using specific certificate attribute and value pairs.

To enable certificate access restriction:

1. Select **Users > User Roles > Select Role > General > Restrictions > Certificate**.
2. Select the **Only allow users with a client certificate signed by Certificate Authority (CA)**.
3. Create a field/value pair check based on attributes within the client certificates. Enter the "Certificate field" and the expected value. Click **Add**. The value in the field depends on the naming attributes in the Relative Distinguished Name(RDN) in the subject DN of the certificate.

For example, if the subject DN is cn=user1, uid=uid1, sn=lastname, E=user1@sample.net, OU=QA, O=company, C=US, you can use 'cn', 'uid', 'sn', 'E', 'ou', 'o', 'c'.

Browser Restriction

To specify browser restrictions:

1. Select **Users > User Roles > Select Role > General > Restrictions > Browser**.
2. Select **Only allow users matching the following user-agent policy** to define browser access control rules.

3. To create a rule:

- For the user-agent string pattern, enter a string in the format `*<browser_string>*`
where asterisk (*) is an optional character used to match any character and `<browser_string>` is a case-sensitive pattern that must match a substring in the user-agent header sent by the browser. You cannot include escape characters `(\)` in browser restrictions.
- Select either:
 - **Allow** to allow users to use a browser that has a user-agent header containing the `<browser_string>` substring.
 - **Deny** to prevent users from using a browser that has a user-agent header containing the `<browser_string>` substring.
- Click **Add**.

4. Click **Save Changes**.

Rules are applied in order, so the first matched rule applies. Literal characters in rules are case sensitive, and spaces are allowed as literal characters. For example, the string `*Opera*` matches any user-agent string that contains the substring Opera.

Authentication Realm

An authentication realm defines the authentication server with which end user is authenticated and the list of restrictions that must be satisfied on the client machine during sign-in. It also provides role mapping option to administrators for configuring the list of roles that needs to be assigned to the user. Role mapping provides flexibility to administrators in configuring how different set of roles need to be assigned to the user.

Creating an Authentication Realm

To create an authentication realm:

1. Select **Administrators > Admin Realms or Users > User Realms**.
2. On the respective Authentication Realms page, click **New**.

User Realms > New Authentication Realm

New Authentication Realm

* Name: Label to reference this realm

Description:

☐ When editing, start on the Role Mapping page

☐ Enable additional authentication server

▼ Dynamic policy evaluation

☐ Enable dynamic policy evaluation

[Save Changes](#)

* indicates required field

3. Enter a name to label this realm and, optionally, a description.
4. Select **When editing, start on the Role Mapping page** if you want the Role Mapping tab to be selected when you open the realm for editing.

5. Under Servers, specify:
 - An authentication server to use for authenticating users who sign in to this realm.
 - (Optional) A directory/attribute server to use for retrieving user attribute and group information for role-mapping rules and resource policies.
 - (Optional) A RADIUS accounting server to use to track when a user signs in and out.
 - Device attributes server to use the device attributes.
6. If you previously selected a RADIUS server for Authentication, the RADIUS Proxy option buttons appear. Select **Proxy Outer Authentication or Proxy Inner Authentication** to allow the system to proxy EAP authentication methods. Select **Do not proxy** if you do not want to use RADIUS proxy.
7. Select Enable additional authentication server to specify an additional authentication server.
8. To use dynamic policy evaluation for this realm, select **Dynamic policy evaluation** to enable an automatic timer for dynamic policy evaluation of this realm's authentication policy, role-mapping rules, and role restrictions. Then:
 - Select the **Refresh interval** option to specify how often to perform an automatic policy evaluation of all currently signed in realm users. Specify the number of minutes (5 to 1440).
 - Select **Refresh roles** to refresh the roles of all users in this realm. (This option does not control the scope of the Refresh Now button.)
 - Select **Refresh resource policies** to also refresh the resource policies (not including Meeting and e-mail Client) for all users in this realm. (This option does not control the scope of the Refresh Now button.)
 - Click **Refresh Now** to manually evaluate the realm's authentication policy, role-mapping rules, role restrictions, user roles, and resource policies of all currently signed-in realm users. Use this button if you make changes to an authentication policy, role-mapping rules, role restrictions, or resource policies and you want to immediately refresh the roles of this realm's users.
 - Click **Save Changes** to create the realm. The General, Authentication Policy, and Role Mapping tabs for the authentication realm appear.

9. Perform the next configuration steps:

- Configure one or more role-mapping rules.
- Configure an authentication policy for the realm.
- After you configure the authentication realm, select **Authentication > Signing In > Signin Policies**, add the realm to a sign-in policy, and associate the realm with an authentication protocol set.

Configuring Admin/User Realm to associate an additional Authentication Server

To configure a user realm:

1. Select **Users > User Realms > New User Realm**.
2. Complete the settings for the user-realm.
3. Under **Additional Authentication Server**, select the **Enable additional authentication server** option.
4. Select any already created authentication-server from the Authentication #2 dropdown.
5. Specify the username and password.

- Username: Specified by user on the sign-in page/Predefined as <USER>.

Configure Predefined as <NTUSER> if Primary Authentication server is AD server.

- Password: Specified by user in sign-in page options/Predefined as <PASSWORD>/Mask static password.

Additional Authentication Server

☒ Enable additional authentication server

You can specify an additional authentication server. The additional credentials can be specified by the user on the sign-in page (the labels for these inputs are specified by the sign-in page), or they can be pre-defined below, in which case the user will not be prompted for the credential.

☐ Enable adaptive authentication

Note: Adaptive authentication is supported by leveraging the behavioral analytics. Enable behavioral analytics on 'System->Behavioral Analytics->Configuration' for supporting this. Adaptive Authentication is not supported with 'Anonymous' type authentication server selected as authenticating server above.

Authentication #2:

AD_204

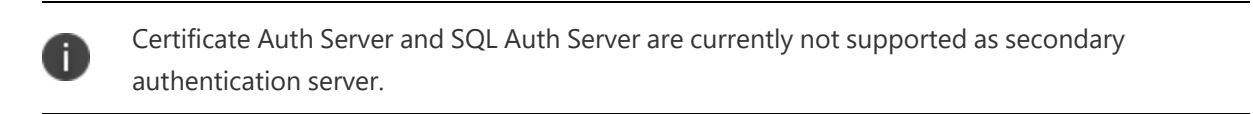

Username is:

☒ specified by user on sign-in page
 ☐ predefined as: <USER>

Password is:

☒ specified by user on sign-in page
 ☐ predefined as: <PASSWORD>
 ☐ Mask static password

☒ End session if authentication against this server fails

1. Select **Users > User Realm > Select Realm > Authentication Policy > Source IP**.
2. Select one of the following options:
 - **Allow users to sign-in** from any IP address- You can allow or deny access to any IP address/netmask combination. For example, you can deny access to all users on a wireless network (10.64.4.100), or you can allow access to all other network users (0.0.0.0).
 - **Allow or deny users from following IP address**- Enter the IPv4/IPv6 address, network/prefix length and choose whether to allow or deny access. Click Add.
3. Click **Save Changes**.

☒ Allow users to sign in from any IP address
☐ Allow or deny users from the following IP addresses:

IPv4/v6 Address	Netmask/Prefix Length	Allow/Deny	
<input type="text"/>	<input type="text"/>	<input checked="" type="radio"/> Allow <input type="radio"/> Deny	<input type="button" value="Add"/>

Note: This restriction will not be enforced if no IP addresses are listed. Add one or more source IP addresses from which users are allowed to sign in or denied access.

Certificate Access Restriction

Certificate access restriction restricts access only to clients that have a client-side certificates. You can further restrict access using specific certificate attribute and value pairs.

To enable certificate access restriction:

1. Select **Users > User Realms > Select Realm > Authentication Policy > Certificate**.
2. Select one of the following options:
 - **Allow all users-** Requires no client certificate.
 - **Allow all users and remember certificate information while user is signed in.**-Client certificate information is saved.
 - **Only allow users with a client certificate signed by Certificate Authority (CA).** – Requires client certificate signed by CA.
3. Create a field/value pair check based on attributes within the client certificates. Enter the "Certificate field" and the expected value. Click **Add**. The value in the field depends on the naming attributes in the Relative Distinguished Name(RDN) in the subject DN of the certificate. For example, if the subject DN is cn=user1, uid=uid1, sn=lastname, E=user1@sample.net, OU=QA, O=company, C=US, you can use 'cn', 'uid', 'sn', 'E', 'ou', 'o', 'c'.
4. Click **Save Changes**.

Browser Restriction

To specify browser restrictions:

1. Select **Users > User Realms > Select Realm > Authentication Policy > Browser**.
2. Select **Only allow users matching the following user-agent policy** to define browser access control rules. To create a rule:
 - For the user-agent string pattern, enter a string in the format `*<browser_string>*` where asterisk (*) is an optional character used to match any character and `<browser_string>` is a case-sensitive pattern that must match a substring in the user-agent header sent by the browser. You cannot include escape characters(\) in browser restrictions.

- Select one of the following options:
 - **Allow to allow users to use a browser that has a user-agent** header containing the <browser_string> substring.
 - **Deny to prevent users from using a browser that has a user-agent** header containing the <browser_string> substring.
 - Click **Add**.
3. Click **Save Changes**. Rules are applied in order, so the first matched rule applies. Literal characters in rules are case sensitive, and spaces are allowed as literal characters. For example, the string *Opera* matches any user-agent string that contains the substring Opera.

User Realms > Users > Authentication Policy > Browser

Password Access Restriction

You can restrict network and resource access by password-length when administrators or users try to sign in. The user must enter a password whose length meets the minimum password-length requirement specified for the realm. Note that local user and administrator records are stored in the local authentication server. This server requires that passwords are a minimum length of 6 characters, regardless of the value you specify for the realm's authentication policy.

To specify password restrictions:

1. Select **Users > User Realms > Select Realm > Authentication Policy > Password**.
2. Select one of the following options:
 - **Allow all users (passwords of any length)** — Does not apply password restrictions on password length.
 - **Only allow users that have passwords of a minimum length** — Requires the user to enter a password with a minimum length that you specify.
3. Select **Enable Password Management** to enable password management. You must also configure password management on the authentication server configuration page (local authentication server) or through an LDAP server.
4. Select **Allow MS-CHAPv2 for Password authentication** to perform password authentication using MS-CHAPv2 protocol to allow single sign-on for Windows desktop clients.

5. Click **Save Changes**. By default, the system requires that user passwords entered on the sign-in page be a minimum of four characters. The authentication server used to validate a user's credentials might require a different minimum length. For example, the local authentication database requires user passwords to be a minimum length of six characters.

The screenshot shows the 'Password' configuration page for an authentication policy. The breadcrumb trail is 'User Realms > Users > Authentication Policy > Password'. The page has three main tabs: 'General', 'Authentication Policy' (which is selected and highlighted with a green arrow), and 'Role Mapping'. Below these are sub-tabs: 'Source IP', 'Browser', 'Certificate', 'Password' (selected), 'Host Checker', 'Limits', and 'RADIUS Request Policies'. The 'Options for primary authentication server' section contains three radio button options: 'Allow all users (passwords of any length)', 'Only allow users that have passwords of a minimum length:' (selected), and a text input for 'Minimum Length' set to '4' characters. Below this is a checked checkbox for 'Enable Password Management' with a descriptive note and a link to the local authentication server configuration page. At the bottom is an unchecked checkbox for 'Allow MS-CHAPv2 for Password Authentication' with its own description. A blue 'Save Changes' button is at the bottom left.

User Realms > Users > Authentication Policy > Password

RADIUS Request Policies

You can create RADIUS request attribute policies to require authentication requests to contain specific RADIUS attribute values. If an endpoint attempts to access a realm with a RADIUS request attribute policy, the endpoint must meet the conditions specified in the policy.

To add a RADIUS request attribute policy to a realm:

- Select a user realm on which you want to implement a RADIUS request attributes policy by selecting **Users > User Realms > Select Realm > Authentication Policy > RADIUS Request Policies**.

2. Click **Add** to populate the Selected RADIUS Request Attributes Policies list from the available RADIUS Request Attribute Policies. The RADIUS request policies selected must be passed to allow users to access a realm. To configure RADIUS request policies, see [here](#).
3. Select the Allow access to realm if any ONE of the selected policies are passed check box if you would like to allow access if any one of the selected policies is passed.
4. Click **Save Changes**.

The screenshot shows the 'RADIUS Request Policies' configuration page. The breadcrumb trail is 'User Realms > Users > Authentication Policy > RADIUS Request Policies'. The page title is 'RADIUS Request Policies'. There are three tabs: 'General', 'Authentication Policy' (which is active and highlighted in green), and 'Role Mapping'. Below the tabs, there is a sub-menu with 'Source IP', 'Browser', 'Certificate', 'Password', 'Host Checker', 'Limits', and 'RADIUS Request Policies' (which is highlighted in green). The main content area contains a text block: 'Restrict the users based on the RADIUS request attributes received from the connecting NAS device. If none of these policies are set then all users will be allowed. By default, a user will be allowed if any one of the selected policies holds true. To configure these policies go to [RADIUS Request Policies](#).' Below this, there are two columns: 'Available RADIUS Request Attribute Policies:' and 'Selected RADIUS Request Attribute Policies:'. The 'Available' column has a dropdown menu showing '(none)'. The 'Selected' column has a dropdown menu showing 'Radius request policy'. Between these columns are 'Add ->' and 'Remove' buttons. At the bottom of the main content area, there is a checkbox labeled 'Allow access to realm if any ONE of the selected policies are passed'. At the very bottom of the page is a 'Save Changes' button.

Configuring Role Mapping

Role-mapping rules are conditions a user must meet to map to user roles.

To specify role-mapping rules for an authentication realm:

1. Select **Administrators > Admin Realms, Users > User Realms**.
2. Select a realm and then click the **Role Mapping** tab.
3. Click New Rule to access the Role Mapping Rule page. This page provides an inline editor for defining the rule.

User Realms > dot1x > Role Mapping > Role Mapping Rule

Role Mapping Rule

Rule based on: Username

* Name:

♥ Rule: If username...

is If more than one username should match, enter one username per line. You can use * wildcards.

♥ then assign these roles

Available Roles: dot1x, Guest, Guest Admin, pulse, remind

Selected Roles: (none)

☐ Stop processing rules when this rule matches

To manage roles, see the [Roles](#) configuration page.

4. In the Rule based on list, select one of the following:

- **Username**—The system username entered on the sign-in page. Select this option if you want to map users to roles based on their usernames. If this is a RADIUS realm, and you are using RADIUS proxy for outer authentication, you cannot configure a role-mapping rule with a username.
- **User attribute**—A user attribute from a RADIUS, or LDAP. Select this option if you want to map users to roles based on an attribute from the corresponding server. This type of rule is available only for realms that use a RADIUS server for the authentication server, or that use an LDAP server for either the authentication server or the directory server. After choosing the User attribute option, click **Update** to display the Attribute list and the Attributes button. Click the **Attributes** button to display the server catalog.
- **Certificate or Certificate attribute**—Certificate or Certificate attribute is an attribute supported by the users' client-side certificate. Select this option to map users to roles based on certificate attributes. The Certificate option is available for all realms. The Certificate attribute option is available only for realms that use LDAP for the authentication or directory server. After choosing this option, click Update to display the Attribute text box.
- **Group membership**—Group membership is group information from an LDAP or native Active Directory server that you add to the server catalog Groups Tab. Select this option to map users to roles based on either LDAP or Active Directory group information. This type of rule is available only for realms that use an LDAP server for either the authentication server or directory server or that use an Active Directory server for authentication. (Note that you cannot specify an Active Directory server as an authorization server for a realm.)
- **Custom Expressions**—Custom Expressions is one or more custom expressions that you define in the server catalog. Select this option to map users to roles based on custom expressions. This type of rule is available for all realms. After you select this option, click Update to display the Expressions lists. Click the Expressions button to display the Expressions tab of the server catalog.
- **Anomaly Attribute**—Select this option for behavioral analytics.

5. Under Rule, specify the condition to evaluate, which corresponds to the type of rule you select and consists of the following:
 - If you are creating a role mapping rule for a MAC address authentication realm, the attributes list cannot be edited. If there is an LDAP server assigned to this MAC authentication server and you want to use and edit the attributes assigned to that LDAP server, please specify the LDAP server as the Directory/Attribute server.
 - Specifying one or more usernames, RADIUS or LDAP user attributes, certificate attributes, LDAP groups, or custom expressions.
 - Specifying to what the value must equate, which might include a list of usernames, user attribute values from a RADIUS or LDAP server, client-side certificate values (static or LDAP attribute values), LDAP groups, or custom expressions.

For example, you can choose a user attribute cookie named "department" from the Attribute list, choose is from the operator list, and then enter "sales" and "eng" in the text box.

Alternatively, you can enter a custom expression rule that references the user attribute cookie named department:

<userAttr.department = ("sales" and "eng")>

6. Under **then assign these roles**:
 - Specify the roles to assign to the authenticated user by adding roles to the Selected Roles list.
 - Select **Stop processing rules when this rule matches** if you want the system to stop evaluating role-mapping rules if the user meets the conditions specified for this rule.
7. Click **Save Changes** to create the rule on the Role Mapping tab. When you finish creating rules, be sure to order role-mapping rules in the order in which you want the system to evaluate them. This task is particularly important when you want to stop processing role-mapping rules when a match is identified.

User Role Evaluation

Administrator can configure the role mapping rules for determining the list of roles that need to be assigned to the users. In case of multiple role assignment, IPS merges the various role settings using permission merge. Administrators can also configure how different rules can be evaluated and merged using the options provided on role mapping rules page.

If you assign a role to a RADIUS proxy realm, role restrictions cannot be enforced. Host Checker policies, source IP restrictions, and any other limits that have been assigned are bypassed. Use RADIUS proxy only if no restrictions have been applied. Additionally, outer proxy cannot be used if a role-mapping rule based on usernames is being used, because the system cannot see the username, and a session cannot be created.

A permissive merge is a merge of two or more roles that combines enabled features and settings according to the following guidelines:

- Any enabled access feature in one role takes precedence over the same feature set to disabled in another role. For example, if a user maps to two roles, one of which disables the Host Enforcer while the other role enables the Host Enforcer, the system enables the Host Enforcer for that session.
- In the case of user interface options, the system applies the settings that correspond to the user's first role.
- In the case of maximum session lengths, the system applies the greatest value from all the roles to the user's session.
- If more than one role enables the Roaming Session feature, then the system merges the netmasks to formulate a greater netmask for the session

The system performs the following security checks before creating a session for a role:

1. The system begins rule evaluation with the first rule on the Role Mapping tab of the authentication realm to which the user successfully signs in. During the evaluation, the system determines if the user meets the rule conditions. If so, then:
 - The system adds the corresponding roles to a list of eligible roles available to the user.
 - The system determines if the "stop on match" feature is configured. If so, then the engine proceeds.
2. The system evaluates the next rule on the authentication realm's Role Mapping tab according to the process in Step 1 and repeats this process for each subsequent rule. When the system evaluates all role-mapping rules, it compiles a comprehensive list of eligible roles.

3. The system evaluates the definition for each role in the eligibility list to determine whether the user complies with any role restrictions. The system then uses this information to compile a list of valid roles, whose requirements the user also meets. If the list of valid roles contains only one role, then the system assigns the user to that role. Otherwise, the system continues the evaluation process.
4. The system evaluates the setting specified on the Role Mapping tab for users who are assigned to more than one role:
 - **Merge settings for all assigned roles**—If you select this option, the system performs a permissive merge of all the valid user roles to determine the overall (net) session role for a user session.
 - **User must select from among assigned roles**—If you select this option, the system presents a list of eligible roles to an authenticated user. The user must select a role from the list, and the system assigns the user to that role for the duration of the user session.
 - **User must select the sets of merged roles assigned by each rule**—If you select this option, the system presents a list of eligible rules to an authenticated user (that is, rules whose conditions the user has met). The user must select a rule from the list, and the system performs a permissive merge of all the roles that map to that rule.

If you use automatic (time-based) dynamic policy evaluation or if you perform a manual policy evaluation, the system repeats the role evaluation process described in this section.

Sign-in Policies

Sign-in policies define the URL's that any user needs to use for accessing the network. IPS provides support for sign-in URL's for administrators and end users. Administrators can login to IPS using the administrator sign-in URL and configure/monitor the server. The user's login using the user sign-in URL's for connecting to the network. The sign-in URL's are configured with authentication realm so that authentication of the users is performed during the sign-in process. Administrators can also use the custom sign-in pages on the sign-in URL's so that pages displayed for the users are customized.

Configuring Administrator Sign-In Policies

To configure administrator sign-in policy:

1. Select **Authentication > Signing In > Sign-in Policies**.
2. To create a new sign-in policy, click **New URL**. To edit an existing policy, click a **URL in the Administrator URLs or the User URLs** column.

New Sign-In Policy

User type: ☐ Users ☒ Administrators

Sign-in URL: Format: <host>[<path>]; Use * as wildcard in the beginning of the host name.

Description:

Sign-in page: To create or manage pages, see [Sign-In pages](#).

▼ **Authentication realm**

Specify how to select an authentication realm when signing in.

☒ **User types the realm name**
The user must type the name of one of the available authentication realms.

☐ **User picks from a list of authentication realms**
The user must choose one of the following selected authentication realms when they sign in. If only one realm is selected, it is automatically used (the sign-in page will not display the list). To create or manage realms, see the [Administrator Authentication](#) page.

Available realms:

Selected realms:

▼ **Configure Signin Notifications**

☐ Pre-Auth Sign-in Notification

☐ Post-Auth Sign-in Notification

3. To create an administrator sign-in policy, select the **Administrators** option button at the top of the page. (By default, the **Users** option button is selected.)

4. In the **Sign-in URL** field, enter the URL to associate with the policy. Use the format <host>/<path> where <host> is the hostname of IPS, and <path> is any string users must enter. For example: users1.yourcompany.com/ic. To specify multiple hosts, use the asterisk (*) wildcard character. For instance:
To specify that all administrator URLs must use the sign-in page, enter */admin.

Use wildcard characters (*) only at the beginning of the hostname portion of the URL. The system does not recognize wildcards in the URL path.

5. (Optional) Enter a **Description** for the policy.
6. From the Sign-in Page list, select the page that you want to associate with the policy. You can select the default page, a variation of the standard sign-in page, or a custom page that you create using the customizable UI feature.
7. For administrator sign-in policies, under Authentication realm, specify which realm maps to the policy, and how users and administrators must choose from among realms. If you select:
 - **User types the realm name**—The system maps the sign-in policy to all authentication realms but does not provide a list of realms from which the administrator can choose. Instead, the administrator must manually enter the realm name into the sign-in page.
 - **User picks from a list of authentication realms**—The system maps the sign-in policy to only the authentication realms that you choose. The system presents this list of realms when the administrator signs in and allows a realm to be chosen from the list. (Note that the system does not provide a list of authentication realms if the URL is mapped only to one realm. Instead, only the realm you specify is displayed).
8. Click the **Add** button to add available realms to the Selected realms box.
9. Click **Save Changes**.

Configuring User Sign-In Policies

To create or configure user sign-in policies:

1. Select **Authentication > Signing In > Sign-in Policies**.
2. To create a new sign-in policy, click **New URL**. To edit an existing policy, click a **URL in the Administrator URLs or User URLs** column.

Signing In > Sign-in Policies > */certauth/

*/certauth/

User type: ☒ Users ☐ Administrators

Sign-in URL: Format: <host>/<path>/; Use * as wildcard in the beginning of the host name.

Description:

System created Certificate Authentication Sign In

Sign-in page: To create or manage pages, see [Sign-In pages](#).

▼ Authentication realm

Specify what realms will be available when signing in.

[Delete](#) [↑](#) [↓](#)

	Available realms	Authentication protocol set	
	<input type="text" value="Cert Auth"/>	<input type="text" value="- Not applicable -"/>	Add
<input type="checkbox"/>	Cert Auth	Cert Auth	

If more than one realm appears above, Odyssey Access Client or the Policy Secure sign-in page will ask the user to choose. Other endpoints cannot choose a realm; the Policy Secure will assign the first suitable realm from the list. If no realms appear above, sign-in will fail.

☐ **User may specify the realm name as a Username suffix**
When this option is selected, the Username suffix will be used to specify a realm

☐ **Remove realm suffix before passing to authentication server**
When this option is selected, the username suffix will be stripped from the Username prior to authenticating with an authentication server

☒ **Fail if suffix does not match any of the realms**
When this option is selected, the user should provide one of the realm as suffix. If not, the user will be denied sign-in.

▼ Configure Guest Settings

☐ Use this sign-in policy for Guest and Guest admin to use specific pages.

▼ Configure SignIn Notifications

☐ Pre-Auth Sign-in Notification

☐ Post-Auth Sign-in Notification

3. In the **Sign-in URL** field, enter the URL that you want to associate with the policy. Use the format <host>/<path>, where <host> is the host name of IPS, and <path> is any string users must enter. For example: users1.yourcompany.com/ic. To specify multiple hosts, use the asterisk (*) wildcard character. For example, to specify that all end-user URLs must use the sign-in page, enter */.
4. Under **Authentication realm**, specify the realms that must be mapped to the sign-in policy. Under Available realms, select realms from the menu. The system maps the sign-in policy only to the authentication realms that you add.

5. Under **Authentication protocol set**, select an authentication protocol set that you have configured previously. If endpoints will connect with a IPS agent, select the default 802.1X protocol set. The protocol set used with a realm must be compatible with the authentication server that is associated with the realm.
6. Click **Add** to add the new realm and authentication protocol pair.
7. Select the **User may specify the realm name as a username suffix** check box to allow non- IPS endpoints to access the system by entering their credentials (in the format *user@realm*).
8. Select the **Remove realm suffix before passing to authentication server** check box for users to enter their credentials with a suffix to send the username without the suffix. Most authentication servers are not compatible with a realm suffix or decorated username.
9. Click **Save Changes**.

Associating Authentication Realms and Protocols with User Sign-in Policies

Different types of endpoints can request authentication through IPS, including IPS agents, third-party 802.1X supplicants (including 802.1X IP phones), switches, and endpoints that request authentication with agentless access.

A IPS agent is software that can use the JUAC protocol. IPS agents include Ivanti Secure Access Client client, and the Java agent. By default, IPS can communicate with IPS agents, the Java agent, and endpoints with agentless access. To accommodate other types of endpoint clients, you might need to create authentication protocol sets within sign-in policies.

When you add a realm in a sign-in policy, you select an authentication protocol set to be used with that realm. There are two default authentication protocol sets. For IPS agents, use the default 802.1X authentication protocol set. For 802.1X IP phones, use the default 802.1X-Phones protocol set.

Third-party 802.1X supplicants cannot use the preconfigured 802.1X protocol set that is used by default with IPS agents. For example, some switches can request authentication using CHAP or EAP-MD5-Challenge. You must define a specific authentication protocol set for these requests.

To define an endpoint's authentication method, you add authentication realms to sign-in policies. You configure authentication protocol sets as required, based on authentication methods that are compatible with the authentication server that you are using. IPS maps the sign-in policy to the authentication realms that you choose. Users who sign in using the URL that you provide have access only to those realms that you specify.

For non- IPS agents, you must select the protocols that the client and the authentication server are compatible with. See the below table for details of what authentication protocols are compatible with different authentication servers.

Protocols	Authentication Servers				
	Certificate	Local	Active Directory	ACE	Mac Auth
EAP-GTC	-	-	-	Y	-
PAP	-	Y	Y	Y	-
CHAP, EAP-MD5-Challenge	-	Y	-	-	-
MS-CHAP	-	Y	Y	-	-
MS-CHAP-V2, EAP-MS-CHAP-V2	-	Y	Y	-	-
EAP-TLS	Y	-	-	-	-
Mac-based auth		-	-	-	Y
EAP-JUAC	Y	Y	Y	Y	-

For 802.1X, AD authentication server used as LDAP is not supported for the following protocols: MS-CHAP, MS-CHAP-V2, and EAP-MS-CHAP-V2.

The decision of what realms are available to the user within a sign-in policy is based on two factors. First, the order of realms in the list is considered. Realms at the top of the list are attempted. Second, the authentication protocol set that you choose must be compatible with the client or supplicant.

To determine a compatible realm, the system looks for a RADIUS subprotocol that is compatible with the client or supplicant's available protocols, and the system automatically selects compatible realms. If the endpoint is using a Ivanti Policy Secure agent, the system presents a list of realms. Any realm with both outer and inner protocols that match the outer and inner protocols on the client is considered compatible.

Protocol compatibility does not guarantee authentication. For example, CHAP and EAP-MD-5 challenge sign-in succeeds only if the stored password is retrievable as clear text. In addition, if the client or supplicant is configured with a non-JUAC protocol (for example, the Windows Vista supplicant), the system searches for a realm without TNC Host Checker restrictions, browser restrictions, or certificate restrictions.

If you are configuring a realm for a Windows client, with a Statement of Health Host Checker policy, you must use an authentication protocol set with the EAP-SOH protocol. When you select EAP-SOH in an authentication protocol set, EAP-SOH is always offered first, regardless of protocol ordering.

If an endpoint is using IPS agent software, the system presents the list of realms to the user or administrator when the user signs in and allows the user to choose a realm from the list. The system does not display a list of authentication realms if the URL is mapped only to one realm. Instead, it automatically uses the realm you specify.

For endpoints that use a non-IPS agent, you can select the User may specify the realm name as a username suffix check box. When the user provides a username with a suffix in the format user@realm, the suffix determines the realm assignment. If you do not select this option, the endpoint is assigned to the first realm in the list whose authentication server is a match with the endpoint's software. For example, if the endpoint's software is configured for tokens (EAP-Generic Token Card), and if the sign in policy permits EAP-GTC, the endpoint is assigned the first realm in the list whose authentication server supports tokens.

When an 802.1X IP phone connects through a realm with the 802.1X-Phone protocol set selected, the device is automatically directed to the proper realm for authentication based on the compatible protocol.

If you are using inner or outer RADIUS proxy with a selected realm, routing with respect to authentication protocols is different. IPS forwards all traffic to a proxy target, which rejects protocols it does not support. With an outer proxy realm, IPS ignores the authentication protocol set. For an inner proxy realm, the authentication protocol set directs IPS as it negotiates the outer protocol (EAP-PEAP or EAP-TTLS) but does not affect the inner protocol.

Managing Sign-In Policies

This topic describes how to configure and manage user sign-in policies.

Enabling and Disabling Sign-in Policies

IPS provides an option to control the list of sign-in URL's that can be used by the users for logging into the network. The Administrator can control the list of sign-in URL's that are allowed for sign-in process using enable/disable functionality. Sign-in URLs that are disabled on Ivanti Policy Secure cannot be used by the users for connecting to the network.

To enable and disable sign-in policies:

1. Select **Authentication > Signing In > Sign-in Policies**.

Signing In > Sign-in Policies

Sign-in Policies

Sign-in Policies Sign-in Pages Sign-in Notifications Authentication Protocol Sets

☐ Restrict access to administrators only

Only administrator URLs will be accessible. Note that Administrators can attempt to sign in even if all rules on this page are disabled.
Warning: Enabling this option will immediately terminate all user sessions.

New URL... Delete... Enable Disable ↑ ↓ Save Changes

	Administrator URLs	Sign-In Page	Authentication Realm(s)	Enabled
<input type="checkbox"/>	*/admin/	Default Sign-In Page	Admin Users	✓
<input type="checkbox"/>				
	User URLs	Sign-In Page	Authentication Realm(s)	Enabled
<input type="checkbox"/>	*/guestadmin/	Default Sign-In Page	Guest Admin (NA)	✓
<input type="checkbox"/>	*/guest/	Default Sign-In Page	Guest (Guest)	✓
<input type="checkbox"/>	*/certauth/	Default Sign-In Page	Cert Auth (Cert Auth)	✓
<input type="checkbox"/>	*/	Default Sign-In Page	Users (802.1X)	✓

2. Select the check box for the policy that you want to change then click **Enable** or **Disable** for enabling or disabling an individual policy.
3. Select or clear the **Restrict access to administrators only** check box at the top of the page to

enable or disable the policy or all user policies.

4. Click **Save Changes**.

Specifying the Order of Evaluation

The IPS evaluates sign-in policies in the same order that you list them on the Sign-in Policies page. When it finds a URL that matches exactly, it stops evaluating and presents the appropriate sign-in page to the administrator or user. For example, for 2 administrator sign-in policies with different URLs:

- The first policy uses the URL `*/admin` and maps to the default administrator sign-in page.
- The second policy uses the URL `yourcompany.com/admin` and maps to a custom administrator sign-in page.

If you list the policies in this order on the Sign-in Policies page, the system never evaluates or uses the second policy because the first URL encompasses the second one. Even if an administrator signs in using the `yourcompany.com/admin` URL, the system displays the default administrator sign-in page. If you list the second policy first, however, the system displays the custom administrator sign-in page to administrators who access the system using the `yourcompany.com/admin` URL.

Note that the system accepts only wildcard characters in the hostname section of the URL and matches URLs based on the exact path. For example, two administrator sign-in policies with two different URL paths:

- The first policy uses the URL `*/marketing` and maps to a custom sign-in page for the entire Marketing Department.
- The second policy uses the URL `*/marketing/joe` and maps to a custom sign-in page designed exclusively for Joe in the Marketing Department.

If you list the policies in this order on the Sign-in Policies page, the system displays Joe's custom sign-in page to him when he uses the `yourcompany.com/marketing/joe` URL to access the system. He does not see the Marketing sign-in page, even though it is listed and evaluated first, because the path portion of his URL does not exactly match the URL defined in the first policy.

To change the order in which administrator sign-in policies are evaluated:

1. Select **Authentication > Signing In > Sign-in Policies**.
2. Select a sign-in policy in the **Administrator URLs or User URLs** list.
3. Click the up or down arrow to change the selected policy's placement in the list.

4. Click **Save Changes**.

Signing In > Sign-in Policies

Sign-in Policies

Sign-in Policies | Sign-in Pages | Sign-in Notifications | Authentication Protocol Sets

☐ Restrict access to administrators only
 Only administrator URLs will be accessible. Note that Administrators can attempt to sign in even if all rules on this page are disabled.
 Warning: Enabling this option will immediately terminate all user sessions.

<input type="checkbox"/>				
	User URLs	Sign-In Page	Authentication Realm(s)	Enabled
<input type="checkbox"/>	*/guestadmin/	Default Sign-In Page	Guest Admin (N/A)	✓

Configuring Sign-In Notifications

With sign-in notifications, you can create and configure detailed notification messages that appear for Ivanti Secure Access Client and for agentless access endpoints when the user attempts to sign in. For example, you can configure a notification message that explains terms of use, company-specific policies, a welcome page, an end user license agreement (EULA), or a message of the day.

For a browser-based (agentless) log in, the notification message appears in a separate page either before (pre-auth) or after (post-auth) user authentication during the sign-in process. For a Ivanti Secure Access Client log in, the notification messages appear in a message box. The user is expected to read the content of the sign-in notification message and acknowledge by clicking a Proceed button. The user may indicate disagreement by clicking a Decline button, which ends the log in attempt.

You can configure a sign-in policy to use a sign-in notification either as pre-auth or post-auth (or both). In the case of post-auth configuration, you can either use a common message for all roles or use separate messages for each role.

You can create a multi-language sign-in notification package that relies on the language setting of the endpoint. You can customize the sign-in notification page appearance for browser-based log ins by modifying the related fields in a sign-in page in the Admin UI or by using a custom sign-in page.

Configuring and Implementing Sign-In Notifications

Sign-in notifications appear for Ivanti Secure Access Client and for browser-based logins when the user attempts to sign in.

To configure and implement sign-in notifications:

1. Select **Authentication > Signing In > Sign-in Notifications**.
2. Click **New Notification**.

The screenshot shows the 'New Sign-In Notification' configuration page. At the top, there is a breadcrumb trail: 'Signing In > Sign-In Notification > New Sign-In Notification'. Below this, the title 'New Sign-In Notification' is displayed in green. The form contains the following fields:

- Name:** A text input field with the value 'New Sign-In Notification'. A tooltip 'Label to reference the sign-in notification.' is visible.
- Type:** Two radio button options: 'Text' (selected) and 'Package'.
- Text:** A large text area containing the message 'You are about to sign in to the system. Do you want to proceed ?'.

At the bottom right of the text area, it says '64 character(s)'. Below the text area, there is a note: 'Text for the sign-in notification. NOTE: For Pulse desktop L3 VPN connections, the combined length of all the sign-in notification messages cannot exceed 3000 characters. If it does then the notifications will not be displayed to the user.' At the bottom left, there is a blue button labeled 'Save Changes'.

3. Specify a Name for the notification. This name appears in the sign-in policies page, and in the UI Options page for a selected role.
4. Select **Text** or **Package**.
 - If you select **Text**, type the desired sign-in notification message, or copy and paste the relevant text into the Text field.
 - If you select **Package**, click the **Browse** button and navigate to a previously prepared .zip file. A package is typically used to provide different language versions of the notification message.
 - The zip file should include a default.txt file and one or more <language>.txt files (Example: en.txt).
 - Language-abbreviations should be strings that can appear in Accept-Language header of an HTTP request.
 - The character encoding supported is UTF-tly.
5. Click **Save Changes**. To enable sign-in notifications:
6. Click **Authentication > Signing In > Sign-in Policies**.

7. Under Configure Sign-in Notifications, select the check box for **Pre-Auth Sign-in Notification**, **Post-Auth Sign-in Notification**, or both.
 - After Pre-Auth Sign-in Notification, select a previously configured sign-in notification from the drop-down menu.
 - After Post-Auth Sign-in Notification, select the option for **Use a common Sign-in Notification for all roles** or **Use the Sign-in Notification** associated to the assigned role.
 - If you select **Use a common Sign-in Notification for all roles**, select a previously configured sign-in notification from the drop-down menu.
 - If you select **Use the Sign-in Notification associated to the assigned role**, the sign-in notification configured for the assigned role will be used.
 - Prevent the Post-Auth sign-in notification from being displayed to users who have seen it before, by selecting the **Skip if already shown** check box. (This is only a hint to the system and might not be honored in all environments.)
8. Click **Save Changes**.
9. You can customize the appearance of the sign-in notification message by selecting **Authentication > Signing In > Sign-in Pages** and creating a sign-in page or using an existing page.

10. Under Sign-in Notification appearance, customize UI options for Pre-Auth Notifications and Post-Auth Notifications by changing the following items:

- For **Notification Title** enter the text that appears at the top of the sign-in notification page.
- In the **Proceed Button** box, enter the text for the button that the user clicks to proceed with the sign-in. This text applies to browser-based log ins only. A Ivanti Secure Access Client log in always displays Proceed.
- Optionally, clear the check box for **Display “Decline” Button**. If this box is not checked, the user does not have the option to decline.
- In the **Decline Button** box, enter the text for the button that the user clicks to decline.
- This text applies to browser-based log ins only. A Ivanti Secure Access Client log in always displays Decline.
- In the **Message on Decline** box, enter the text that you would like to appear when a user clicks the Decline button.

11. Click **Save Changes**.

If you enabled **Use the Sign-in Notification associated to the assigned role** you must complete the implementation by selecting the sign-in notification on the Users > User Roles > Role Name > General > UI Options page or Administrators > Admin Roles > Role Name > General > UI Options page, as applicable.

If more than one role is available to a user, the sign-in notification associated with the first role assigned is displayed.

12. Add the sign-in page in which you have customized the sign-in notification appearance to the sign-in policy.

Configuring Sign-In Pages

A sign-in page defines the customized properties in the end-user's welcome page such as the welcome text, help text, logo, header, and footer. The system allows you to create two types of sign-in pages to present to users and administrators:

Configuring Standard Sign-In Pages

Standard sign-in pages are included with the default system. You can modify standard sign-in pages. You can modify the default sign-in page that the system displays at sign-in. You can also create new standard sign-in pages that contain custom text, logo, colors, and error message text.

To create or modify a standard sign-in page:

1. Select **Authentication > Signing In > Sign-in Pages**.
2. Click **New Page**. To modify an existing page, select the link for the page you want to modify.
3. Enter a name to identify the page.
4. In the Custom text section, revise the default text used for the various screen labels. When you add text to the Instructions field, you can format text and add links using the following HTML tags: `<i>`, ``, `
`, ``, and `<ahref>`. However, the system does not rewrite links on the sign-in page (because the user has not yet been authenticated), so point only to external sites. Links to sites behind a firewall will fail.

If you use unsupported HTML tags in your custom message, the system might display the end-user's home page incorrectly.

5. (Optional) In the Header appearance section, specify a custom logo image file for the header and a different header color.
6. (Optional) In the Custom error messages section, revise the default text that is displayed to users if they encounter certificate errors.

You can include `<<host>>`, `<<port>>`, `<<protocol>>`, and `<<request>>` variables and user attribute variables, such as `<<userAttr.cn>>` in the custom error messages. These variables must be in the format `<variable>` to distinguish them from HTML tags that have the format `<tag>`.

7. (Optional) To provide custom help or additional instructions for your users, select **Show Help** button, enter a label to display on the button, and specify an HTML file to upload. Note that the system does not display images and other content referenced in this HTML page.

1. Select **Authentication > Signing In > Sign-in Pages**.
2. Click **Sample** to download the Sample Folder as ZIP and save it on local disk.

Signing In > Sign-In Page > Custom Sign-In Pages

Custom Sign-In Pages

Custom sign-in pages allow you to provide customized templates for various pages that may appear during the sign-in process. Refer to the documentation for information about creating valid templates.

▼ Sign-In Pages

Name:

Label to reference the custom sign-in pages.

Page Type: ☒ Access

☐ Use Custom Page for the Pulse Desktop Client Logon

The Pulse Desktop Client will open a web browser and use custom pages for authentication instead of standard login prompts.

☐ Prompt the secondary credentials on the second page

These labels appear when a realm using this sign-in page specifies a secondary authentication server that requires user input. These are only applicable to user sign-in pages.

This option is not applicable when TOTP authentication server is selected as secondary auth-server for this realm, in which case token input from user is always taken from the second page.

Templates File: No file chosen

Zip file containing the custom templates and assets.

Current Template File:

sample.zip Size 196808 bytes Uploaded on Tue Oct 4 11:44:53 2016

☐ Skip validation checks during upload

Sample Templates Files

The following sample templates may be useful in producing your own customized sign-in page templates. Click to download the sample files, edit them to fit your needs, and then upload them.

Sample
This is a basic set of templates that works for most cases.

Softid
This is a set of templates for ACE Authentication.

Kiosk Example
This is an example which demonstrates how to protect against hardware keystroke loggers.

Notices:

WARNING: Page PleaseWait is out of date. It is recommended you re-customize this page from the latest sample zip file

3. Copy the following files after unzipping the folder (locally saved in previous step):

- UserAdmin-add-user.shtml
- UserAdmin-add-bulk-users.shtml
- UserAdmin-update-user.shtml
- Logout.shtml
- PleaseWait.shtml

4. Open the previously downloaded Sample Custom Sign-in folder and replace the files.

5. Select all the files and create *.ZIP file for uploading custom sign-in page.
6. Upload the new custom sign-in page and click **Save Changes**.

Using the Initial Setup Wizard

Overview

The initial setup wizard allows you to quickly configure IPS to ensure that the IPS device is configured effectively and efficiently. You can open the initial setup wizard through Wizards > Initial Setup > Configure. As a best practice, it is recommended to configure Profiling as a first step so that all the network devices are discovered. You can then launch the wizard to configure the enforcement policies on the discovered devices.

Using the initial setup wizard, you can configure IPS for the following use cases:

- Network visibility using Profiler functionality
- Layer 2 enforcement through 802.1X, MAC authentication, and SNMP for endpoints.
- Easy deployment for guest or BYOD access

Benefits

The initial setup wizard provides the following benefits:

- Provides quick onboarding of existing Ivanti Connect Secure (ICS) users to IPS with a mechanism to import existing ICS policy configuration into IPS.
- Allows users to easily and quickly deploy IPS based for the desired use case (network visibility, enforcement, and guest access).

Prerequisites

You must keep the following information ready before configuring the IPS device:

- NTP server address and other details.
- The license SKU or license server details. The IPS appliance is added as a license client with necessary licenses to be leased.
- Authentication servers (AD/LDAP) must have groups defined for different roles so that corresponding access can be configured for L2 enforcement use case.

- The list of switches along with IP address and other parameters such as VLAN information for different set of users.
- Administrator account details of ICS for fetching the authentication server and role details.
- Fingerprint database, subnets to scan, and switch details for Profiling the network.

Limitations

The following are the limitations:

- Supports only layer 2 enforcement use cases.
- The initial setup wizard is supported only with the new UI.
- You can configure each use case only once using the wizard and cannot edit the configurations once it is completed.

Configuring IPS using Initial Setup Wizard

This section covers the configuration using initial setup wizard.

You can launch the initial setup wizard using:

- Select **Wizards > Initial Wizard > Configure**
- Select **Wizards > Initial Wizard > Configuration Summary**

The configuration summary page shows the configured/ not configured use cases and the corresponding details. It is recommended to configure the use cases using the configuration summary page.

The following figure shows the configuration summary page for a fresh installation.

Initial Setup > Initial Setup Configuration Summary

Initial Setup Configuration Summary

Pulse Policy Secure supports different use cases and across the various devices and platforms. Initial Setup Wizard helps in configuring below use cases

- Profiler to get the visibility of all the devices present in the network
- Enforcement for the devices connecting in the network using 802.1x, MAC Authentication and SNMP Authentication mechanisms
- Guest Access to enable guest users to login to the network along with provision of self registration for guest users

Note: It is recommended to configure the profiler first so that devices in the network are discovered. After the profiling of the network is done, wizard can be launched again to configure the enforcement policies for the discovered device types. Additionally, Guest Access functionality can also be enabled.

- › Common Configuration Details
- › Profiling Configuration Details
- › Enforcement Configuration Details
- › Guest Access Configuration Details

Basic Settings

Configuring System Date and Time

The time synchronization between IPS and another component is very critical. You can easily configure the system date and time using the initial setup wizard. The system date and time can be configured manually or you can configure a network time protocol (NTP) server. It is recommended to use a public NTP server for time synchronization.

To set the system date and time:

1. Select **Wizards > Initial Setup > Configure**.
2. Select the deployment use case.

3. Select your time zone. Selecting the appropriate time zone enables the system to automatically adjust the time for Daylight Saving Time changes.
 - Use NTP Server- Enter the fully qualified domain name or IP address for the NTP server.
 - Set Time Manually- Enter the date (MM/DD/YY) and time. You can click Get from Browser to automatically populate the Date and Time.
4. Click **Set Date and Time**.

The screenshot shows the 'Initial Setup' wizard with a sidebar on the left containing the following menu items: Introduction, Use Cases, System Settings (highlighted in green), Switch Configuration, Enforcement, Pulse Connect Secure Configuration, Authentication Servers, Roles, and Summary. The main content area is titled 'Date and Time' and includes the following elements:

- Select TimeZone:** A dropdown menu showing '(GMT-12:00) Eniwetok, Kwajalein'.
- Time Source Selection:** Two radio buttons. 'Use NTP Server' is selected, with an adjacent text input field containing 'NTP server'. 'Set Time Manually' is unselected, with an adjacent empty text input field.
- Get from Browser:** A blue button with a clock icon and the text 'Get from Browser'.
- Example Time:** A text label '@example: 12/28/2016 10:51:39 AM'.
- Set Date & Time:** A blue button.
- Licenses Section:**
 - License Keys:** A large, empty rectangular text area.
 - Configure License Server:** A green link with a right-pointing arrow.
 - Install License:** A blue button with a document icon.
- License Summary:** A table at the bottom showing 'localhost2 (500 users)' and '0 licenses'.

At the bottom of the wizard are three buttons: 'Cancel', '< Previous', and 'Next >'.

Configuring License

The license can be applied in 2 ways:

- Manually by entering the license key
- License Server

To apply the license manually:

1. Enter the license keys obtained through license key generation.
2. Click **Install License**.

The screenshot shows the 'Initial Setup' wizard with a sidebar menu on the left containing: Introduction, Use Cases, System Settings (highlighted), Switch Configuration, Profiling, Guest Access, Enforcement, Pulse Connect Secure Configuration, Authentication Servers, Roles, and Summary. The main content area is titled 'Initial Setup' and has two tabs: 'Set Time Manually' (selected) and 'Get from Browser'. Under 'Set Time Manually', there is a date/time input field showing '2/14/2017 12:12:57 PM' and an example '@example: 12/28/2016 10:51:39 AM'. A 'Set Date & Time' button is present. Below this is the 'Licenses' section, which includes a 'License Keys' text area containing a sample key: 'PULSEC-ADD-10000- sunrise-well-pique-holiday-four-wings-hornbead-square-office-sunrise-hornbead'. A green arrow points to a 'Configure License Server' link. Below that is an 'Install License' button. A green success message bar states 'Installed New License Keys'. At the bottom, a table displays the installed license details:

	localhost2 - (1000 users) Licensing Hardware ID: 0274M7RKS0CVJ0HDE	1 license
	Pulse Policy Secure License 1000 Concurrent Sessions - Perpetual <small>Key: sunrise-well-pique-holiday-four-wings-hornbead-square-office-sunrise-hornbead</small>	Permanent

To configure through the license server:

1. Enter IP address or hostname of license server.
2. Enter a unique ID for the client. This ID is used to communicate and verify the client with the license server.
3. Select the network to communicate with the license server from the Preferred Network menu. The available options are internal (default), external, and management.

4. Select the **Verify SSL Certificate** check box if you want the client to verify the server's SSL certificate when establishing communication with it.

Configure License Server

Server IP/Hostname: 1.1.1.1

Lease Client ID: xxx

Password: ***

Preferred Network: internal

☐ Verify SSL Certificate

Configuring Profiling for Network Visibility

Profiler dynamically identifies and classifies endpoints across managed and unmanaged endpoint devices, so that access to network and resources can be controlled based on the type of the device. It also helps you to get visibility so that necessary security policies for corporate access, BYOD, and guest access can be enforced.

To enable profiling on your network:

1. Select **Enable Profiling to get visibility of devices in the network**.

Initial Setup

Use cases and Features

(Note: It is recommended to configure the profiler first so that devices in the network are discovered. After the profiling of the network is done, wizard can be launched again to configure the enforcement policies for the discovered device types.)

- ☒ Enable profiling to get visibility of devices in the network
- ☐ Enable enforcement and authentication mechanisms for the devices connecting to the network
- ☐ Fetch configuration details from another Pulse Connect Secure server
- ☐ Enable guest access for providing access to guest users

Prerequisite

Below are the details required for configuring PPS through this wizard

- **License Details**
License SKU or License server details are required. In case of license server, this PPS box needs to be added as a license client with necessary licenses to be leased configured
- **Profiling Details**
Fingerbank database, Subnet and Switch details for profiling the network and provide visibility
- **Switch Details**
List of switches that we want to be used for providing the access to the end users and different VLANs on the switch for different set of users.

Cancel < Previous Next >

2. Configure system date and time. See [Configuring System Date and Time](#)
3. Configure license. See [Configuring License](#)
4. You can add an SNMP device manually through Add New Switch configuration or automatically discover SNMP devices through Device Discovery.

5. To discover SNMP v2 devices:

- Select the SNMP version as v2
- Enter the IP address/range and community string.

Configuring Layer 2 Enforcement

The following enforcements are supported for the devices connecting to the network.

- 802.1X
- MAC Authentication
- SNMP

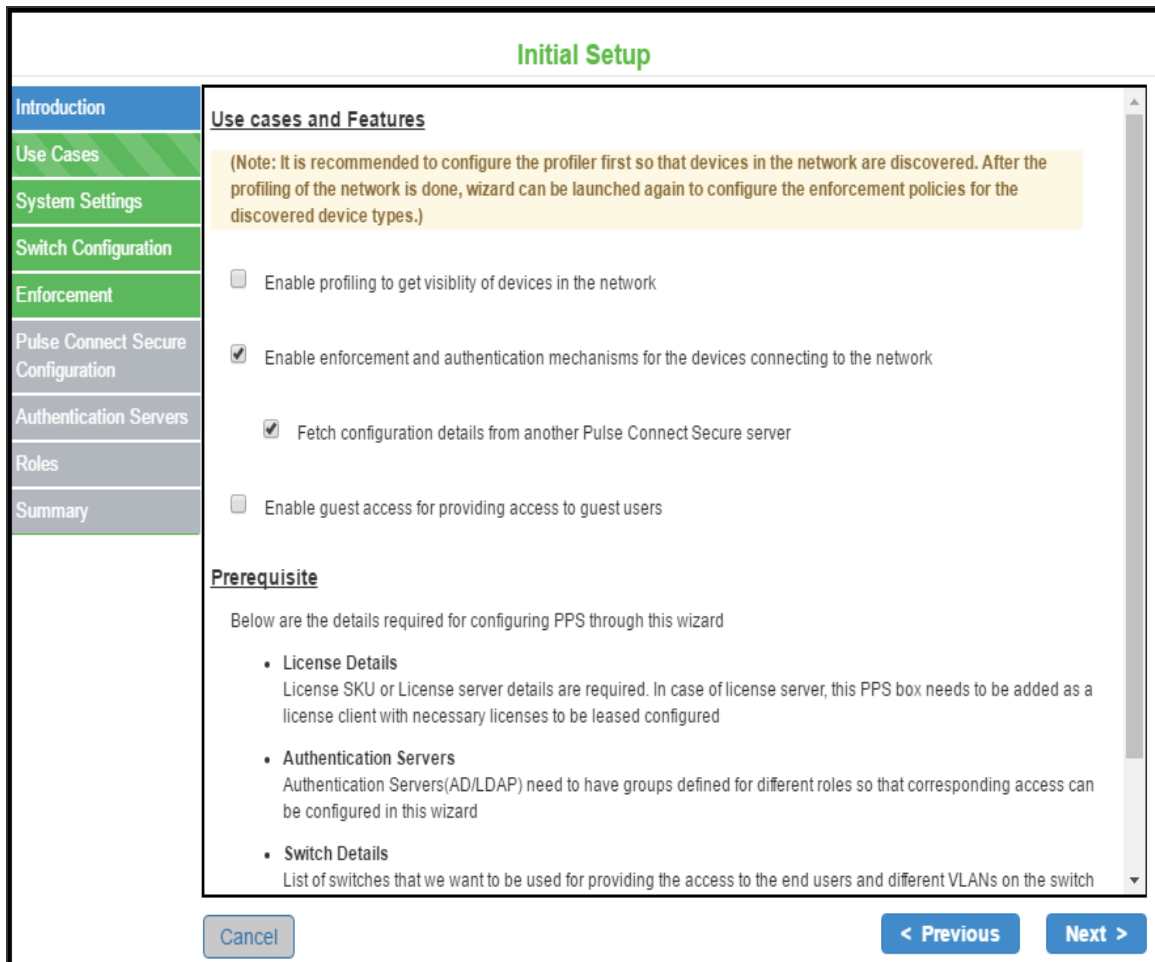

Before you begin:

As a best practice, it is recommended to configure Profiling as a first step so that all the network devices are discovered. You can then launch the wizard to configure the enforcement policies on the discovered devices.

To configure enforcement and authentication mechanism:

1. Select **Enable enforcement and authentication mechanism for the devices connecting to the network.**

 Profiling is enabled by default when you enable enforcement and authentication.

The screenshot shows the 'Initial Setup' wizard interface. On the left is a sidebar with navigation links: Introduction, Use Cases, System Settings, Switch Configuration, Enforcement, Pulse Connect Secure Configuration, Authentication Servers, Roles, and Summary. The 'Enforcement' link is highlighted in green. The main content area is titled 'Initial Setup' and contains two sections: 'Use cases and Features' and 'Prerequisite'. The 'Use cases and Features' section has a yellow note box stating: '(Note: It is recommended to configure the profiler first so that devices in the network are discovered. After the profiling of the network is done, wizard can be launched again to configure the enforcement policies for the discovered device types.)'. Below this are four checkboxes: 'Enable profiling to get visibility of devices in the network' (unchecked), 'Enable enforcement and authentication mechanisms for the devices connecting to the network' (checked), 'Fetch configuration details from another Pulse Connect Secure server' (checked), and 'Enable guest access for providing access to guest users' (unchecked). The 'Prerequisite' section is titled 'Prerequisite' and contains the text 'Below are the details required for configuring PPS through this wizard'. It lists three prerequisites: 'License Details' (License SKU or License server details are required), 'Authentication Servers' (Authentication Servers(AD/LDAP) need to have groups defined for different roles), and 'Switch Details' (List of switches that we want to be used for providing the access to the end users and different VLANs on the switch). At the bottom of the wizard are three buttons: 'Cancel', '< Previous', and 'Next >'.

Initial Setup

Use cases and Features

(Note: It is recommended to configure the profiler first so that devices in the network are discovered. After the profiling of the network is done, wizard can be launched again to configure the enforcement policies for the discovered device types.)

- ☐ Enable profiling to get visibility of devices in the network
- ☒ Enable enforcement and authentication mechanisms for the devices connecting to the network
- ☒ Fetch configuration details from another Pulse Connect Secure server
- ☐ Enable guest access for providing access to guest users

Prerequisite

Below are the details required for configuring PPS through this wizard

- License Details**
License SKU or License server details are required. In case of license server, this PPS box needs to be added as a license client with necessary licenses to be leased configured
- Authentication Servers**
Authentication Servers(AD/LDAP) need to have groups defined for different roles so that corresponding access can be configured in this wizard
- Switch Details**
List of switches that we want to be used for providing the access to the end users and different VLANs on the switch

2. Configure basic settings. See Basic Settings.

3. Configure the switch. Complete the configurations as described in the following table.

Discover Switches	
SNMP v2	<ul style="list-style-type: none"> Enter the IP address/range and community string. Enter the IP address/range
SNMP v3	<ul style="list-style-type: none"> Select the desired Authentication protocol and Privacy protocol. Enter the Authentication password and Privacy password. Click the search icon.
Add New Switch	
Name	Enter a name to label the RADIUS client. You can assign any name to a RADIUS client entry, use the device's SSID or IPv4/IPv6 address to avoid confusion.
IP Address	Enter the IPv4/IPv6 address of the switch.
Make/Model	Select the make/model of the switch vendor. The make/model selection tells IPS which dictionary of RADIUS attributes to use when communicating with this client.
RADIUS Client Configuration	
IP Address Range	Enter the number of IP addresses in the IP address range for the switch/WLC, starting with the address you specified for IP Address. You can specify a range up to a maximum of 32,768 addresses.
Shared Secret	Enter the RADIUS shared secret. A RADIUS shared secret is a case-sensitive password used to validate communications between IPS and switch.
SNMP Configuration	

Discover Switches	
SNMP Version	<ul style="list-style-type: none">• Select the SNMP version (v2/v3).• For SNMP v2, enter the read community string.• For SNMPv3, enter the authentication password, privacy password and select the authentication protocol and privacy protocol.• Select Use for enforcement to use the SNMP device for SNMP enforcement.

Importing Configurations from Ivanti Connect Secure

Importing Configurations from Ivanti Connect Secure

The existing configurations in ICS can be imported to IPS for quickly configuring the IPS device.

The following configurations can be imported from ICS:

- Authentication servers
- Role names
- Host Checker compliance policies

To import the ICS device configurations to IPS device:

1. Select **Fetch configuration details from another Connect Secure server.**
2. Enter the ICS sign-in URL.
3. Enter the admin username.
4. Enter the password
5. Enter the realm information.
6. Click **Fetch**. The list of imported authentication servers, roles, and Host Checker compliance policies are displayed.

If you try to import the configuration multiple times. The configurations will be overwritten with the newer configuration.

Authentication Server

Authentication server is used for authentication and verifying group membership. It validates the user credentials and then provides the required access. It also maps users to roles based on either Light Weight Directory Access protocol (LDAP) or Active Directory (AD) group information. The initial setup wizard supports AD and LDAP authentication servers for user authentication. LDAP is supported for device authentication based on MAC address.

To add the authentication server:

1. Select the **Server Type** (AD/LDAP).

The screenshot shows the 'Initial Setup' wizard with the 'Authentication Servers' tab selected in the left sidebar. The main content area is titled 'What Authentication Servers do you have?'. It contains two dropdown menus for 'User Authentication' (set to 'AD') and 'MAC Authentication' (set to 'ldap'). Below these is a 'List of available Servers' section with an 'Add Server Type' dropdown set to '- Add New Server -'. A table lists the configured servers:

AuthServer Name	AuthServer Type	Domain/HostName	
ldap	LDAP	10.209.114.249:389	
AD	ACTIVE_DIRECTORY	pcsqalab	

At the bottom, there are 'Cancel', '< Previous', and 'Next >' buttons.

2. For Active Directory, enter the server name, user credentials, Kerberos realm, and domain. You

can click Test to verify the configuration.

- Configure the required authentication server for user authentication and machine authentication.

Roles

A user role defines user session parameters (session settings and options) and personalization settings (user interface customization).

You can reuse the roles imported from ICS and then configure the VLAN and group information.

To add a role name:

1. Enter the role name and VLAN information.
2. Select the **AD group or LDAP group**.

If the AD or LDAP group information is not available you must add the group information manually.

3. Click **Add (+)** icon.
4. Enter the remediation role and the VLAN information.
5. Enter the role name and the VLAN information for unmanaged devices.

Compliance Check

IPS offers a variety of endpoint host checks to ensure compliance, including predefined checks for third-party endpoint security software including anti-virus, firewall, anti-malware/anti-spyware applications.

You can reuse the compliance policies from ICS.

To configure IPS for endpoint compliance:

1. Enter the rule name.
2. Select the platform type- Windows, Linux, MAC.
3. Select the rule type.

Antivirus, Firewall, and Process policies are supported for Windows and MAC platforms.
Process policy is supported for Linux platform.

4. To enable remediation action, select **Enable Remediation Action**.

5. Click + **Add**.

Configuring Guest Authentication

Guest access feature on IPS enables guest users to access the network through a self-registration process. The guest users self-register for network access from their device. Upon successful registration, the guest users are notified with the user credentials and other details through SMS or email.

To configure guest authentication:

3. Enter the VLAN information for the guest user.

The screenshot shows the 'Initial Setup' wizard with the 'Guest Access' tab selected in the left sidebar. The main content area is titled 'Do you want to configure Guest Access?' and includes a description: 'Guest Access feature is used for providing access to guest users. Guest users can go through self registration process for obtaining credentials and login to the network using them.'

The configuration fields are as follows:

- Guest Users VLAN:** 65
- ☒ **Create Guest Administrator Account**
 - UserName:** adminuser
 - Password:** [masked]
- ☒ **Enable Self Registration**
- ☒ **Send Email to Guest Users**
 - SMTP Server:** abc.xyz.net
 - Email Address:** qwr@xyz.net
 - Login:** qwerty
 - Password:** [masked]
- ☒ **Send SMS to Guest Users**
 - Gateway:** Clickatell
 - Gateway URL:** api.clickatell.com
 - Login Name:** name
 - Password:** [masked]
 - API Product ID:** 12345
 - Mobile No:** +91 xxxxxxxxxx

At the bottom, there are three buttons: 'Cancel', '< Previous', and 'Next >'.

4. (Optional) Select **Create Guest Administrator Account** and enter the username and password.
5. (Optional) Select **Enable Self Registration**.
The SMTP and SMS configuration settings must be configured to enable guest users to create user accounts on their own.
6. (Optional) Select **Send Email to Guest Users** and then enter the IP address or host name of the SMTP server, email address, and log in credentials of the SMTP server.
7. (Optional) Select **Send SMS to Guest Users** and then select the SMS gateway type, gateway URL, SMS gateway log in credentials, API ID, and the mobile number of the guest user.
8. Configure the switch as described in table.

Add New Switch	
Name	Enter a name to label the RADIUS client. You can assign any name to a RADIUS client entry, use the device's SSID or IPv4/IPv6 address to avoid confusion.
IP Address	Enter the IPv4/IPv6 address of the switch.
Make/Model	Select the make/model of the switch vendor. The make/model selection tells IPS which dictionary of RADIUS attributes to use when communicating with this client.
RADIUS Client Configuration	
IP Address Range	Enter the number of IP addresses in the IP address range for the switch/WLC, starting with the address you specified for IP Address. You can specify a range up to a maximum of 32,768 addresses.

The following figure shows the final configuration summary page. You can verify the common configuration, profiling, enforcement, guest access configuration details.

Initial Setup > Initial Setup Configuration Summary

Initial Setup Configuration Summary

The progress bar shows four steps: Profiler, Enforcement, Guest Access, and End. Each step has a green checkmark icon above it. The 'End' step is highlighted with a blue 'Configure' button to its right.

Step	Status
Profiler	Completed
Enforcement	Completed
Guest Access	Completed
End	Ready to Configure

Pulse Policy Secure supports different use cases and across the various devices and platforms. Initial Setup Wizard helps in configuring below use cases

- Profiler to get the visibility of all the devices present in the network
- Enforcement for the devices connecting in the network using 802.1x, MAC Authentication and SNMP Authentication mechanisms
- Guest Access to enable guest users to login to the network along with provision of self registration for guest users

Note: It is recommended to configure the profiler first so that devices in the network are discovered. After the profiling of the network is done, wizard can be launched again to configure the enforcement policies for the discovered device types. Additionally, Guest Access functionality can also be enabled.

IPS Migration Wizard

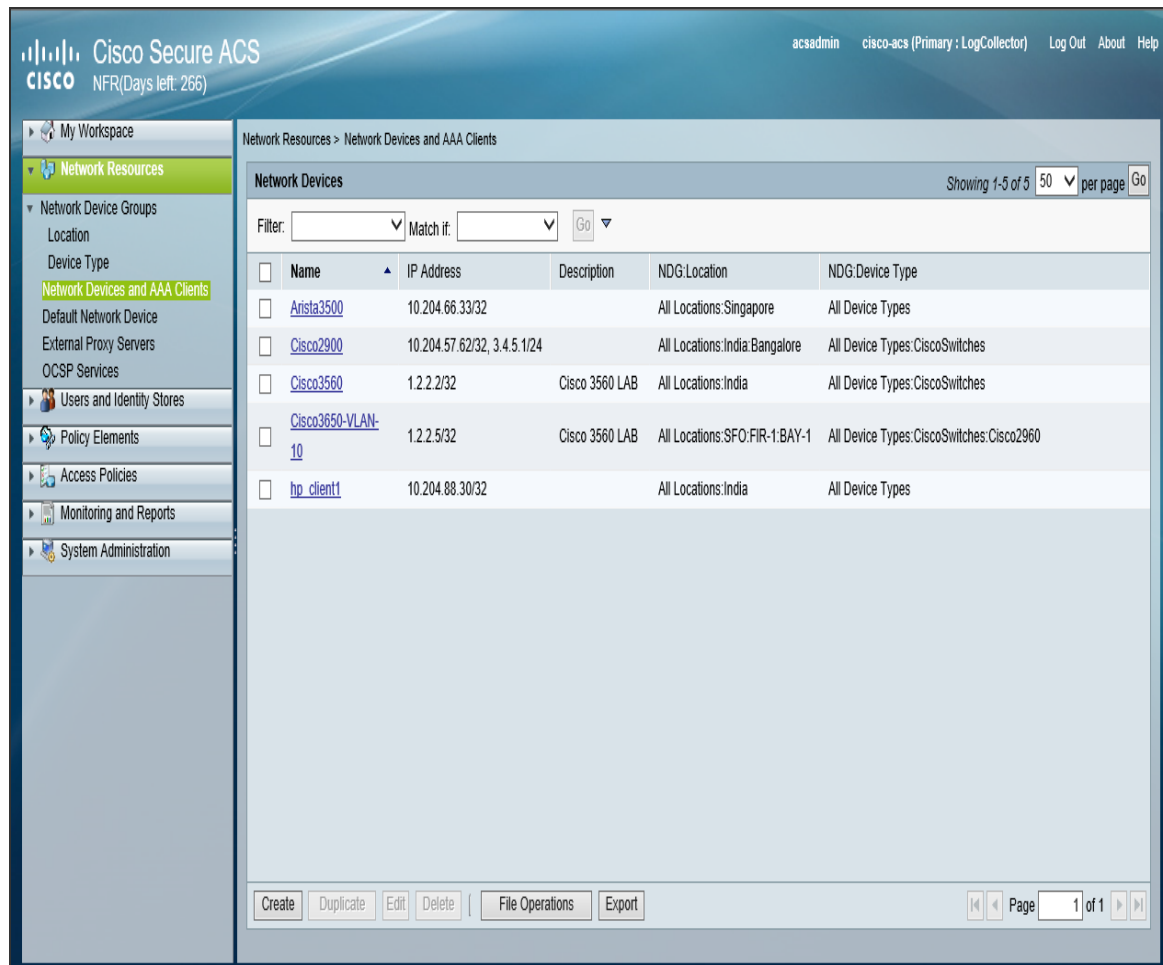

IPS Migration wizard enables seamless migration of RADIUS and TACACS+ configuration, and also automatically creates basic IPS configuration needed for these use cases to work right after migration is complete.

Prerequisites

Before proceeding with the IPS Migration wizard, export the RADIUS/TACACS+ clients' details in the form of CSV file from Cisco ACS.

Follow the below steps to export the RADIUS/TACACS+ clients' details:

1. Log in to Cisco ACS GUI.
2. Navigate to **Network Resources > Network Devices and AAA Clients**.
3. Select all the clients.

4. Click **Export**.

Configuring RADIUS and TACACS+ Migration using IPS Migration Wizard

The IPS Migration wizard helps administrators in creating RADIUS and TACACS+ configuration using the CSV file exported from Cisco ACS.

To configure RADIUS and TACACS+ migration using IPS Wizard:

1. Log in to the IPS Admin console.
2. Select **Wizards > Migration > RADIUS and TACACS+ config migration**. The Introduction window lists the configuration steps.

3. Click **Next**.

The screenshot shows a window titled "RADIUS and TACACS+ config migration". On the left is a vertical sidebar with a list of steps: "Introduction" (highlighted in green), "Import File", "Authentication Server", "Return Attribute Policies", "Shell Policies", and "Summary". The main area of the window contains the following text:

This wizard helps in creating RADIUS and TACACS+ configuration using CSV file. As part of this, below are the various functionalities that can be configured

- Creation of Radius clients, Return attribute policies for 802.1x authentication.
- Creation of TACACS+ clients, Shell policies for device administration.
- Authentication server for authenticating the users.

At the bottom of the window, there are three buttons: "Cancel" on the left, and "< Previous" and "Next >" on the right.

4. In the Import File window, choose the use cases for configuration import – the **RADIUS clients** check box or **TACACS+ clients** check box or both. Based on these selections, migration wizard provides steps to create the Radius policies followed by the Shell policies.
5. Click **Browse** and select the CSV file that is exported from Cisco ACS.

6. Click **Next**. After receiving confirmation for successful upload, click **Next**.

The screenshot shows a window titled "RADIUS and TACACS+ config migration". On the left is a sidebar with a list of steps: Introduction, Import File (highlighted in green), Authentication Server, Return Attribute Policies, Shell Policies, and Summary. The main area of the window displays a green message box stating "Successfully validated file chosen. Click on 'Next' to continue with the configuration." Below this, there are two checked checkboxes: "RADIUS clients" and "TACACS+ clients". Further down, there is an "Upload File (csv)" label, a blue "Browse" button, and the filename "export-net-type.csv". At the bottom left of the window is a "Cancel" button, and at the bottom right are "< Previous" and "Next >" buttons.

At any stage of the migration wizard, you can click **Previous** to go back to the previous window or click **Cancel** to cancel the migration.

7. Next step is to configure the Active Directory server. You can select one from the existing list of AD servers or add a new AD server.
- To select from the existing list, click **Select existing server** and choose the required AD server from the list.
 - To add a new AD server, click **Add new AD server**. Enter the name, domain name, Kerberos realm, user name, password that matches with the ACS configurations.
8. Click **Test** to validate the Active Directory configuration. This will take a few seconds to complete.

9. Once the validation is successful, click **Next**.

RADIUS and TACACS+ config migration

☒ Return Attribute:

Return Attribute	Value	Action
Filter-Id		+
Filter-Id	compliant.in	🗑️

☐ Add Session-Timeout attribute

☒ Terminate the session ☐ Re-authenticate the session

For more information on 802.1X authentication and troubleshooting, see 802.1X Authentication with Cisco Switch cook book

Layer 2 Enforcement

Layer 2 enforcement means controlling network access at the point where the user attaches to the network. In a wired network, this control is at the switch port; in a wireless network the control is at the wireless access point. The network access control is accomplished through 802.1X authentication protocol (implemented on the switch or wireless AP) in conjunction with RADIUS return attributes to control switch or AP operation such as VLAN assignment and filtering.

Using the 802.1X standard we can create a strong network perimeter defense through strong admission controls that do not allow users onto the network unless they are compliant with specified policy.

Policy Enforcement using 802.1X

Overview

802.1X is an IEEE standard for port-based network access control. It provides an authentication mechanism for devices and users attempting to connect to wired and wireless LANs so that only authorized connections are allowed.

The basic components of 802.1X are:

- **Endpoints**- The endpoint is the device being authenticated. The supplicant is an agent running on the endpoint. For example, Ivanti Secure Access Client, native supplicant, and third party supplicant.
- **Authenticator/Switch**-The authenticator is a network device a managed switch or wireless access point that facilitates authentication by relaying credentials between the supplicant and authentication server.
- **Authentication Server**- IPS acts as an authentication server (typically a RADIUS server) and validates the credentials of the supplicant requesting access.

The 802.1X standard specifies the Extensible Authentication Protocol (EAP) as its encrypted message format for transmission between supplicant and authenticator.

Benefits of 802.1X Authentication

Following are the benefits of 802.1X authentication:

- Supports dynamic authentication policy using 802.1X, RADIUS, and RADIUS proxy.
- Supports RADIUS Change of Authorization (CoA) and RADIUS Disconnect, which allows devices to change the VLAN/ACL for the endpoint based on roles.
- Supports hybrid NAC deployment (802.1X for wireless network and SNMP for wired network).
- Supports backend third-party RADIUS servers through RADIUS proxy.
- Supports native client, Ivanti Secure Access Client, and third party supplicants.

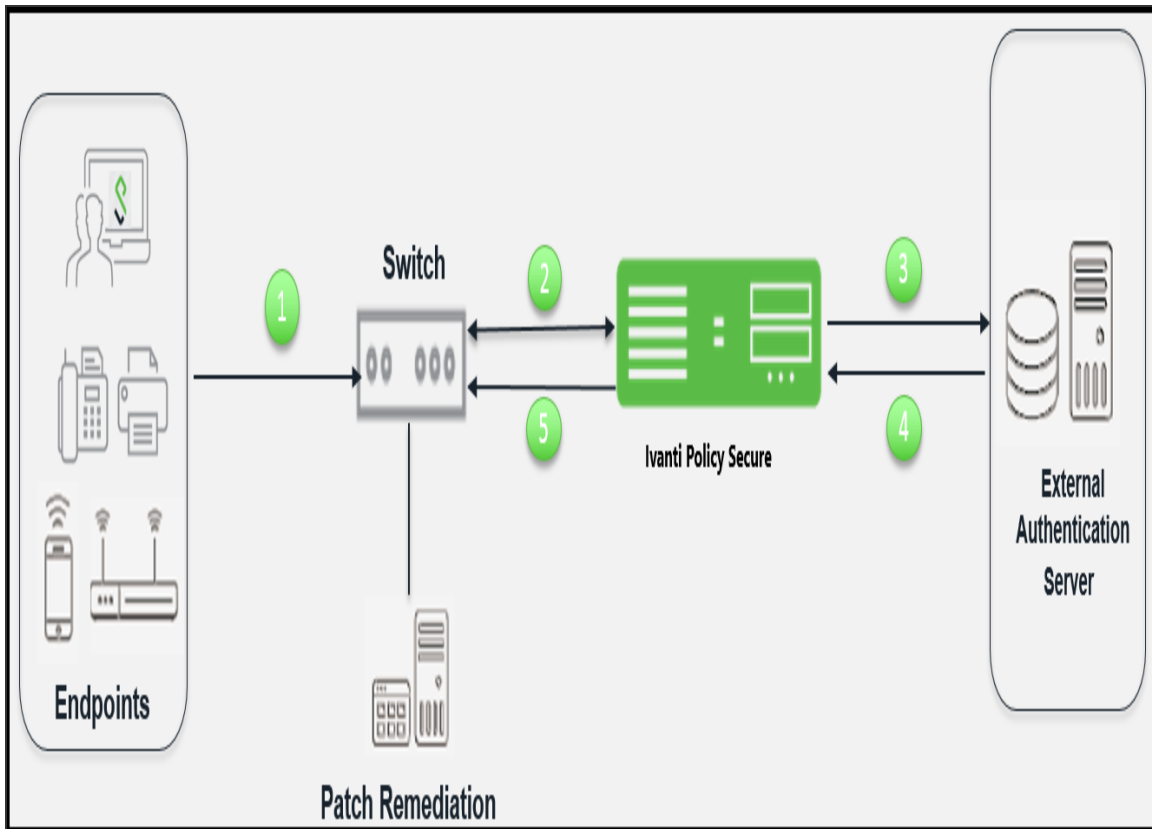

Deployments using 802.1X Authentication

The 802.1X provides authenticated access to LAN, which applies to both wireless and wired networks. In a wireless network, the 802.1X authentication occurs after the client has associated to an access point using an 802.11 association method. The wired networks use the 802.1X standard without any 802.11 association by connecting to a port on an 802.1X enabled switch.

Using 802.1X, the user is authenticated to the network by means of user credentials, such as a password, certificate, or a token card. The keys used for data encryption are generated dynamically. The authentication is not performed by the switch, but rather by IPS as the RADIUS server. The 802.1X method uses EAP messages to perform authentication. The newer EAP protocols can dynamically generate the Wired Equivalent Privacy (WEP), Temporary Key Integrity Protocol (TKIP), or Advanced Encryption Standard (AES) keys that encrypt data between the client and the wireless access point. Dynamically created keys are more difficult to break than preconfigured keys because their lifetime is much shorter. The known cryptographic attacks against WEP can be prevented by reducing the length of time that an encryption key remains in use. The encryption keys generated using EAP protocols are generated on a per-user and per-session basis. The keys are not shared among users, as they must be with preconfigured keys or preshared passphrases.

Deployment of IPS with External Authentication Server

It is difficult or impossible to maintain a centralized database of users in environments with many distributed users. You can easily pair IPS with an organization's other identity databases, such as LDAP and Active Directory to leverage existing credentials. IPS RADIUS server can forward authentication requests from a network access device (NAD) to an external Authentication server.

The authentication process is described below:

1. The endpoint connects to an 802.1X enabled switch/WLC. The endpoint exchange EAP messages using 802.1X, which contain information about user credentials and the health of the endpoint.
2. The switch receives the request and starts the RADIUS authentication with IPS.
3. IPS receives the request and then converts the request to the required format for the external authentication server.
4. If IPS successfully authenticates the user, it sends a message to the switch/WLC to allow the endpoint access to the network. The type of access granted depends on the user's identity and the health of the endpoint. For example, if the endpoint meets the requirements of all Host Checker policies, the user can have full network access. If the endpoint does not meet some security requirements, the user can be granted access to a remediation server. If the endpoint is using Ivanti Secure Access Client as its 802.1X supplicant, IPS and the endpoint exchange messages as necessary throughout a session (for example, to monitor the endpoint's security compliance). If the endpoint is using a native supplicant, Host Checker is not supported.

5. If the endpoint is using Ivanti Secure Access Client, and the endpoint meets the requirements of all Host Checker policies then IPS allows user to access the protected resources.

The user's identity and the endpoint health assessment are used to determine which VLAN to use for the switch port that the endpoint is connected to. Typically, if the endpoint does not meet minimum criteria for health assessment as defined by the administrator, the endpoint will be placed on a restricted VLAN which allows access to servers which can aid in remediating the endpoint.

You define VLAN policies for endpoints that access switches using 802.1X. After an authenticated endpoint, has been mapped to a set of roles, the VLAN policies are evaluated and the VLAN information is communicated to the switch through RADIUS attributes. RADIUS attributes vary by make and model of switch. You specify the make and model when configuring a RADIUS client on IPS.

In addition to authenticating endpoints with 802.1X IPS RADIUS server can be used to authenticate 802.1X IP phones, switches.

Deployment of IPS as a RADIUS Server

IPS provides the RADIUS server functionality for layer 2 enforcement. Using the IPS internal RADIUS server, you can provision 802.1X authentication for endpoints. Layer 2 authentication and enforcement is used to control network access policies at the edge of the network using an 802.1X enabled switch or access point.

A RADIUS license allows you to use the IPS series device as a RADIUS appliance. To apply your initial license or to upgrade your license, select System > Configuration > Licensing in the left navigation pane.

The authentication process is described below:

1. The endpoints connect to switch over 802.1X using EAP protocol.
2. The switch receives the request and starts the RADIUS authentication with IPS.
3. IPS integrated RADIUS server receives the request and performs the authentication and then returns the attributes for controlling user access.
4. The switch uses the returned attributes to control the user access privileges on the port or service set identifier (SSID).

The following RADIUS configuration options are available only with RADIUS license.

- Host Checker Custom: Statement of Health policy- When you apply both a RADIUS license and an MS-NAP license, you can configure an Endpoint Security policy by way of the Host Checker policy. If you have only a RADIUS license, the Endpoint Security menu is not available.
- RADIUS User Count- This feature allows you to create RADIUS users. To view the number of RADIUS users, select System > Status. The number of RADIUS users does not count against the concurrent user license if you have both a RADIUS license and a user license installed.

The following features are not available with RADIUS only license:

- Infranet Enforcer
- Host Enforcer
- Endpoint Security
- Push Configuration
- MDM Authentication servers
- Sign-in Notifications
- Agent and Agentless tabs do not appear on the Overview page.
- Enterprise onboarding

Deployment of IPS as a RADIUS Proxy

In environments with many distributed users, it can be difficult or impossible to maintain a centralized database of users. Using RADIUS proxy, IPS RADIUS server can forward authentication requests from a network access device (NAD) to an external RADIUS server.

You can configure IPS to proxy RADIUS inner or outer authentication to an external RADIUS server. Proxying inner or outer authentication gives you the flexibility to direct requests for authentication through whatever realm is most appropriate for each user.

The authentication process when using an external authentication server is described below:

1. The endpoints connect to switch.
2. The switch receives the request and starts the RADIUS authentication with IPS.
3. IPS receives the request and then forms another RADIUS request and forwards it to the external RADIUS server.
4. If authentication succeeds the IPS assigns the user the appropriate roles, and then passes the associated RADIUS attributes back to the access device.

With RADIUS proxy enabled, IPS acts as a simple relay agent and does not participate in the accounting and authorization process. You must configure all attributes for authenticator configuration on the external RADIUS server.

You can specify the outer or inner proxy as follows:

- Outer proxy requires that the external RADIUS server presents a certificate to the supplicant. The result is a secure tunnel between the supplicant and the external server.

- Inner proxy uses the IPS certificate to establish the secured tunnel, but relays the supplicant authentication data to the external RADIUS server. The secured tunnel is established between the supplicant and IPS. The data passes between the IPS and the external RADIUS server in clear text.

Configuring 802.1X on IPS

This section covers the configuration for 802.1X authentication. It involves configuring the various elements necessary for performing 802.1X authentication between the endpoint and IPS.

802.1X authentication is also supported on external port. As a prerequisite, the Admin must enable Global Setting with Auth Traffic Control option. For configuration procedure, see ["AAA Traffic Management" on page 562](#)

Configuring Authentication Protocol Set

Authentication protocol is a method of defining how endpoints are authenticated through IPS. IPS supports a set of authentication protocols. You can configure sign-in policy with combination of authentication protocol set and associate them with realms to determine how endpoints connect and authenticate using 802.1X. The IPS supports a variety of EAP and non-EAP authentication methods to allow you to determine how endpoints authenticate. For example, you can use the default EAP methods with Ivanti Secure Access Client, or you can use different methods to permit authentication with different endpoints, such as third party 802.1X supplicants and IP phones.

For IPS agents (Ivanti Secure Access Client and Host Checker agentless access), authentication is supported through EAP-TTLS and EAP-PEAP as the outer protocols and EAP-JUAC (a proprietary protocol) by default.

EAP-TTLS first authenticates the server and sets up an encrypted Transport Layer Security (TLS) tunnel for secure transport of authentication information. Within the TLS tunnel, a second authentication protocol is used to authenticate the user. EAP-TTLS is the "outer" authentication, while the second protocol is the "inner" authentication.

The following is a list of supported EAP types:

EAP-PEAP uses server-side public key certificates to authenticate clients with server. The PEAP authentication creates an encrypted SSL / TLS tunnel between the client and the authentication server. The exchange of information is encrypted and stored in the tunnel ensuring the user credentials are kept secure.

- EAP-JUAC is a proprietary protocol that enables host check, firewall provisioning, and IP address restrictions.
- EAP-TTLS uses server-side certificates to set up authentication between clients and servers.
- EAP-SoH allows the endpoint to exchange state of health messages with IPS to assess endpoint qualification for passing Statement of Health rules in a Host Checker policy. It is used only with Windows native 802.1X supplicants.
- EAP-Generic Token Card (EAP-GTC) supports the use of authentication tokens.
- PAP supports the exchange of plaintext passwords.
- CHAP support includes MS-CHAP, MS-CHAPv2, EAP-Message Digest 5 (EAP-MD5), and EAP-MS-CHAPv2
- Password Authentication Protocol (PAP) with plain-text passwords.
- EAP Transport Layer Security (EAP-TLS) allows third party 802.1X supplicants to authenticate through a certificate authentication server.

IPS supports these authentication protocols as non-tunneled authentication methods as well as inner authentication methods, depending on the policies that you configure. You can configure protocol sets with or without EAP, with the exception of MD5, EAP-GTC, EAP-TLS, and EAP-SOH, which are supported only for EAP. To use EAP-SOH, you must use EAP-PEAP as an outer authentication protocol.

If you use a protocol set with inner and outer authentication, both protocols must match the inner and outer protocol that is configured for the endpoint.

IPS uses two default preconfigured protocol sets.

- 802.1X protocol set that is used by default with IPS agents.
- 802.1X-phones protocol set that is used for authenticating 802.1X IP phones.

Third-party supplicants cannot use the preconfigured 802.1X protocol set. For example, some switches can request authentication using CHAP, or EAP-MD5-Challenge. For such devices, you must define an authentication protocol set.

Outer	Inner	Basis	Usage recommendation
PAP [1]	n/a	Password	Local auth server, Active Directory, LDAP [2] Cisco switch authentication
CHAP [1]	n/a	Password	Captive portal or authentication of switch administrators for HP ProCurve switch
EAP-MD5-Challenge [1]	n/a	Password	Captive portal or authentication of switch administrators, some IP phones
MS-CHAP [1]	n/a	Password	
MS-CHAP-V2 [1]	n/a	Password	
EAP-MS-CHAP-V2 [1]	n/a	Password	
EAP-GTC [1]	n/a	Token	
EAP-TLS	n/a	User Certificate	802.1X supplicant, some IP phones

Outer	Inner	Basis	Usage recommendation
EAP-PEAP			Third party 802.1X supplicant
	EAP-MS-CHAP-V2	Password	Local or Active Directory server
	EAP-GTC	Token	802.1X supplicant
	EAP-TLS	User Certificate	
	EAP-JUAC	Various	Ivanti Secure Access Client
	EAP-SOH	System Health	Windows supplicant with Statement of Health Host Checker policy
EAP-TTLS			Ivanti Secure Access Client, other supplicant
	PAP		LDAP authentication server
	CHAP		
	EAP-MD5-Challenge		
	MS-CHAP		
	MS-CHAP-V2		
	EAP-MS-CHAP-V2		Local or Active Directory server
	EAP-GTC		802.1X supplicant
	EAP-JUAC		Ivanti Secure Access Client

The following additional information is intended to help you understand the protocols that have been implemented for our 802.1x solution:

- Ivanti always uses EAP-TTLS/EAP-JUAC.
- EAP-TTLS, EAP-PEAP, and EAP-TLS are based on TLS and therefore secure. We recommend protecting other protocols by putting them into an EAP-TTLS or EAP-PEAP tunnel, if the supplicant supports one of these tunnels.
- With LDAP, there are 3 protocol possibilities:
 - If the LDAP server is also an Active Directory server, configure the server on IPS as an Active Directory server, not as an LDAP server. On IPS, PEAP-MS-CHAP-V2 is enabled by default. You can also enable MS-CHAP and MS-CHAP-V2 if necessary.
 - If passwords in the LDAP server are stored irreversibly hashed, CHAP family protocols will not work, only PAP and TTLS-PAP will work. On IPS TTLS-PAP is enabled by default. You can enable PAP if required, but this is the least secure protocol.
 - Some LDAP servers allow you to store the passwords in clear text or reversibly encrypted. In this situation, all the CHAP family protocols will work.

During RADIUS authentication, if a user's password has expired then the user is prompted to change the password if the protocol is:

- EAP-MSChapV2
- PEAP with EAP-MSChapV2
- TTLS with EAP-MSChapV2
- TTLS with Non-EAP MSChapV2
- Plain Non-EAP MSChapV2
- EAP-JUAC

The following table summarizes additional usage guidelines.

- Password- The protocols that support password changing on IPS include JUAC, MS-CHAP-V2, EAP-MS-CHAP-V2, and EAP-GTC. If you use CHAP, PAP or MS-CHAP for a Layer 2 connection (for example, with an Active Directory Server), password changing is not supported through IPS.
- Expired passwords- You can direct users with expired passwords to a Web interface to access a default VLAN to allow users to log in with a clear text password and change their password.

- Password restrictions- Password restrictions (for example, password length) cannot be enforced if you use the CHAP family protocols for authentication.
- Default protocols for Ivanti- The 802.1X protocol set is used by default for endpoints that connect to Ivanti Secure Access Client. If you disable the JUAC protocol (a proprietary protocol) on Ivanti Secure Access Client IPS and have only the features of a standard third party supplicant.

To configure an authentication protocol set:

1. Select **Authentication > Signing In > Authentication Protocols**.

The default 802.1X protocol set is configured with EAP-TTLS and EAP-PEAP as primary (outer) authentication protocols.

EAP-JUAC, EAP-MSCHAP- V2 are used as inner authentication for EAP-PEAP.

EAP-JUAC, PAP, MSCHAP- V2, EAP-MS-CHAP-V2, or EAP-GenericTokenCard are used as inner authentication for EAP-TTLS.

To create a new protocol set, click **New Authentication Protocol**, or select the check box beside the existing 802.1X protocol set and click **Duplicate**.

Signing In > Authentication Protocols > New Authentication Protocol

New Authentication Protocol

Name: Label to reference this Authentication Protocol.

Description:

▼ **Authentication Protocol**

Specify authentication protocols in preferred order

Available protocols:		Selected protocols:
CHAP	Add ->	EAP-TTLS
EAP-GenericTokenCard	Remove	EAP-PEAP
EAP-MD5-Challenge		
EAP-TLS		
MS-CHAP		

▼ **PEAP**

If EAP-PEAP is selected in authentication protocol and is not used for inner proxy, specify inner authentication protocols in preferred order

Available protocols:		Selected protocols:
EAP-GenericTokenCard	Add ->	EAP-JUAC
EAP-SOH	Remove	EAP-MS-CHAP-V2
EAP-TLS		

▼ **TTLS**

If EAP-TTLS is selected in authentication protocol and is not used for inner proxy, specify inner authentication protocols in preferred order

Available protocols:		Selected protocols:
CHAP	Add ->	EAP-JUAC

		EAP-MS-CHAP-V2
		EAP-GenericTokenCard

Save Changes

2. Enter a name, and optionally a description for the new authentication protocol set. You select the protocol set by name when you create a sign-in policy.
3. Under Authentication Protocol, select authentication protocol(s) from the Available Protocol list. Click **Add**.
4. For non-tunneled protocols, create an authentication protocol set, which includes CHAP, PAP or EAP-MD5 Challenge.
5. If you select EAP-PEAP as the main authentication protocol, under PEAP select an inner authentication protocol from the Available Protocol list. Click **Add**.
6. If you select EAP-TTLS as the main authentication protocol, under TTLS select an inner authentication protocol from the Available Protocol list. Click **Add**.

If you are using inner RADIUS proxy, do not select an inner protocol with EAP-PEAP or EAP-TTLS.

7. Click **Save Changes** to save your selections. When you configure a sign-in policy, you associate this authentication protocol set with an authentication realm.

Creating and modifying the sign-in policy

Sign-in policies define both the URLs that users and administrators use to access the network and to view the sign-in pages. IPS has two types of sign-in policies—one for users and one for administrators. When you configure sign-in policies, you associate realms, sign-in pages, and URLs that are provided for users when they first log in.

To modify the authentication protocol set used by a specific authentication realm:

1. Select **Authentication > Signing In > Sign-In Policies** and click **New URL**.

Signing In > Sign-In Policies > New Sign-In Policy

New Sign-In Policy

User type: ☒ Users ☐ Administrators

Sign-in URL: Format: <host>[:<path>]. Use * as wildcard in the beginning of the host name.

Description:

Sign-in page: To create or manage pages, see [Sign-In pages](#).

▼ **Authentication realm**

Specify what realms will be available when signing in.

<input type="checkbox"/>	Available realms	Authentication protocol set	
<input type="checkbox"/>	<input type="text" value="Cert Auth"/>	<input type="text" value="- Not applicable -"/>	<input type="button" value="Add"/>
<input type="checkbox"/>			

If more than one realm appears above, Odyssey Access Client or the Policy Secure sign-in page will ask the user to choose. Other endpoints cannot choose a realm; the Policy Secure will assign the first suitable realm from the list. If no realms appear above, sign-in will fail.

☐ **User may specify the realm name as a username suffix**

When this option is selected, the username suffix will be used to specify a realm

☐ **Remove realm suffix before passing to authentication server**

When this option is selected, the username suffix will be stripped from the username prior to authenticating with an authentication server

☒ **Fail if suffix does not match any of the realms**

When this option is selected, the user should provide one of the realm as suffix. If not, the user will be denied sign-in.

- Under **Authentication realm**, add a new realm or modify an existing realm.
- Select the desired authentication protocol set.
- Click **Save Changes**.

Configuring a Location Group

Location groups let you organize or logically group network access devices by associating the devices with specific sign-in policies. Sign-in policies provide a way to define and direct independent access control policies with the network. For example, you can create location group policies to logically group the switch/WLC in each building at a corporate campus. You can also use location group policies to specify a special realm for MAC address authentication.

To configure a location group:

1. Create a sign-in policy to associate with the location group.
2. Select **Endpoint Policy > Network Access > Location Group**.

Network Access > Location Group > New Location Group

New Location Group

✓ Location Group

* Name: Label to reference this Location Group.

Description:

* Sign-In Policy: To manage policies, see the [Sign-In Policies](#)

MAC Authentication Realm: To manage realm, see the [MAC Address Realms](#)

[Save Changes](#)

* indicates required field

3. On the New Location Group page, enter a name to label this location group and optionally a Description.
4. For Sign-in Policy, select the sign-in policy associate with the location group.
5. Click **Save Changes**.

Location groups allows you to block Layer 2 endpoints in specific locations from using particular authentication protocols, realms, and roles. For example, you can block endpoints in unsecure locations from accessing sensitive roles. However, RADIUS clients should not be placed in insecure locations. To ensure that RADIUS clients are not compromised and do not violate these policies, all the network RADIUS clients should be securely protected.

Configuring the network access device as a RADIUS Client

A RADIUS client policy specifies the information required for an 802.1X network access device to connect as a RADIUS client of the IPS.

-  If you specify the Switch Address as IPV6, IPS will allow Ivanti Secure Access Client to connect only using Client's IPV6 address in 802.1x Connection Type.

- ~!@#\$%^&*()_+|\=-'{}[]:"';<>?/.,

9. (Support for RFC 6218: Cisco/Airespace Switches). If you are configuring a new RADIUS authentication server and want to enable AES key wrap, which makes the shared secret between the controller and the RADIUS server more secure, follow these steps:

- Enable the Key Wrap checkbox.
- From the Key Wrap Format drop-down list, choose ASCII or HEX to specify the format of the AES key wrap keys: Key Encryption Key (KEK) and Message Authentication Code Key (MACK)
- Enter the 16-byte KEK used for encrypting the key generated by the server
- Enter the 16-64 bytes MACK used for authenticating the messages.

AES key wrap is designed for Federal Information Processing Standards (FIPS) customers and requires a key-wrap compliant RADIUS authentication server.

10. For **Location Group**, select the location group to use with this NAD.
11. Under **Dynamic Authorization support**, Select the **Support Disconnect Messages** check box to send disconnect messages to supplicants if access is no longer authorized. If this check box is selected, a disconnect request is sent to the NAD any time a session is deleted. IPS can also send disconnect messages upon a role event that includes a VLAN change or a change in RADIUS attributes.
12. Select **Support CoA Messages** to enable CoA messages and disconnect messages support for the client. Ensure that Ivanti Secure Access Client is configured with EAP-JUAC in EAP-TTLS inner protocol as most preferred protocol.
- RADIUS CoA feature provides a mechanism to change the attributes of an authentication, authorization, and accounting (AAA) session after it is authenticated. Using the existing session, RADIUS CoA allows devices to change the VLAN/ACL for the endpoint based on roles. CoA works on role mapping associated with every user. As the device state changes, the user is put in to various roles based on the Host Checker assessment or compliance check. During the dynamic assessment, CoA requests such as filter-id or any other return attributes that suites the role is sent to the NAD to provide the required access for the device. IPS receives CoA-NAK request if the NAD is not able to apply filter-id or any other return attributes.
13. (Optional) Enter a new **Dynamic Authorization Port** (Default port is 3799). The default port might vary depending on the manufacturer. NAD listens to UDP port to receive RADIUS CoA messages from IPS.

14. Click **Save Changes**.

Configuring Role and Role Mapping

IPS access management framework evaluates authentication requests to match endpoints to roles. You must configure user roles for the various types of endpoints authenticated.

To create a user role:

1. Select **Users > User Roles**.
2. Click **New Role**.
3. Complete the name and description configuration and then save the configuration.

The screenshot shows the 'New Role' configuration page. At the top, there is a breadcrumb 'User Roles > New Role' and a green heading 'New Role'. Below this, there are two input fields: 'Name:' with a text box containing a single character, and 'Description:' with a larger text area. Below the input fields, there is a green heading 'Options' with a downward arrow. Under 'Options', there is a note: 'Session and appearance options are specified in Default Options. Check the following if this role should override these defaults.' Below the note, there are five checkboxes: 'Session Options' (checked), 'UI Options' (checked), 'Odyssey Settings for Access' (unchecked), 'Odyssey Settings for Preconfigured Installer' (unchecked), and 'Enable Guest User Account Management Rights' (unchecked). At the bottom left, there is a blue button labeled 'Save Changes'.

4. Click **Agent** and deselect agent options and then save the configuration.

User Roles > Users > Agent > General

☐ Hide the Agentless page after Captive Portal redirect

With this option, the Browser splash page will not appear after Captive Portal authentication. As a result, heartbeats will not be sent and the session will timeout unless option [Allow VPN Through Firewall](#) is enabled.

[Save Changes](#)

Role mapping rules define how endpoints are assigned to roles.

To configure the role mapping rules for User Realms:

1. Select **Users > User Realm**.
2. Click **New** to display the User Realm configuration page and create a user realm.
3. Click the **Role Mapping** tab to display the role mapping configuration page for the realm.
4. On the role mapping configuration page, click **New Rule** to display the role mapping rule configuration page.
 - (Optional) For Name, enter a name to label this role mapping rule.
 - Select the rule from the Rule based list and provide the appropriate details.
 - Select the appropriate role and click **Add**.
5. Click **Save Changes** to save the configuration.

Configuring RADIUS Attributes Policies

This section describes the configuration information for RADIUS return attributes policy that is applied on switch, request attribute policy, which can be used along with sign-in policies for realm selection, policy realm restrictions, and authentication/accounting reporting for RADIUS authentication events.

Configuring RADIUS Return Attributes

RADIUS attributes policies sends the return list of attributes to an 802.1X switch. For example, you can specify which VLAN endpoints must be used to access the network. You can also configure other functions on a NAD's port based on the role assigned to the user who is currently using that port. For example, a Switch might let you use return list of attributes to configure Quality-of-Service (QoS) functions (Bandwidth or Priority) on the device's port based on the current user's role.

A return list is a set of attributes that IPS returns to the NAD after authentication. The return list usually provides additional parameters that the NAD needs to complete the connection. Return list attributes are authorization configuration parameters.

In the RADIUS attributes policy, you can select RADIUS attributes by name from a predefined list. For each attribute, you specify values using strings or numbers. By default, IPS sends a session timeout value on all RADIUS accepts that is equal to the timeout value of the configured session length. You can bypass the default timeout.

To configure a RADIUS attributes policy:

1. Select **Endpoint Policy > Network Access > RADIUS Attributes**.
2. Click **New Policy**.

Network Access > Radius Attributes > RADIUS Return Attributes > Full Access Policy

Full Access Policy

General

* Name: Full Access Policy Required: Label to reference this policy.

Description:

Location Group

Specify the Location Group for which this policy applies.

Available Location Groups: Default, Guest, Cert Auth, Guest Wired, HP Test Location

Selected Location Groups: Cisco Test Location

Selected Radius Clients

Below list is populated dynamically based on the selected Location Groups

Vendor (Manufacturer)	Client Details
Cisco Systems	Cisco 3850

Access Control Policy Settings

Select below option to control the access level for the device/user connecting to the network.

☐ Provide full Access (Open Port)

☒ Control the Access

Access can be controlled using the VLAN ID, ACLs and Radius Return Attribute settings below

☒ Control using VLAN ID: 80 (1 - 4094)

Specify the PPS interface to which end points will connect while they are assigned to above VLAN

☒ Automatic ☐ Internal ☐ External

☒ Control access using Access Control List (ACL) settings (Supported only for Cisco, Juniper, HP)

Specify the ACL mode for controlling the device access

☐ ACL Name:

☒ ACL Rule(s)

Delete

Protocol	Destination IP / Network	Destination Port	Action
ip			permit
tcp	10.204.89.245	443	permit
tcp	10.204.89.246	443	deny

☒ Control access using Radius Return Attributes

Note: These attributes are sent to switch for controlling the access

Return Attribute	Radius Auth Server Attribute Value	Auth Server Catalog Attribute Value	Value
Filter-Id	-none-	-none-	
Filter-Id	-none-	-none-	PERMIT-ALL in

☒ Add Session-Timeout attribute

Specify the action that needs to be taken for the device upon expiration of session timeout on the switch

☒ Terminate the session ☐ Re-authenticate the session

Note: This will send session timeout attribute equal to session lifetime

Roles

Select the roles to which this policy is applicable

☐ Any Role ☒ Selected below ☐ Other than selected below

Available roles: Agentless_full_role, Agentless_rem_role, Compliant Role, Eng, Guest

Selected roles: ENGG

NOTE: Any changes to this page results in termination of existing L2 connections and triggers reconnections.

Save Changes Cancel

3. On the New Policy page, enter a name for the policy.
4. (Optional) For Description, enter a description for the policy.

5. Under Location Group, select the location groups to which you want to apply this policy, and click **Add**. To apply the policy to all location groups, do not add any location groups and use the default setting (all) listed in the Selected Location Groups list. The selected Radius clients table is dynamically updated based on the selected Location Groups.

6. Under Access Control Policy Settings, select from the following options:

- **Provide full Access (Open Port)**-Check this option if you do not want to assign endpoints to a VLAN or return any RADIUS attributes. Selecting this check box disables all other RADIUS Attributes options.

- **Control the Access**-Select this option to control access using VLAN ID, ACLs and RADIUS return attributes.

Control using VLAN Id: Enter the VLAN ID (1-4094) used for assigning devices to corresponding VLAN on the switch.

- For Interface, specify IPS network interface that endpoints affected by this policy to use to connect to IPS:
- **Automatic (use configured VLANs)**-Select this option to use VLAN tagging. You must also connect the internal interface to the trunk port on a VLAN-enabled Switch that sees all the VLAN traffic.
- **Internal**- Select this option if the endpoints using this RADIUS attributes policy should use the IP address of the internal interface.
- **External**-Select this option if the endpoints on the configured VLAN should use the IP address of the external interface.

Control access using Access Control List (ACL) settings (Supported only for Cisco, Juniper, HP)

- Specify the ACL Name for controlling the device access or specify the ACL Rule to be applied on the Switch.
- Select the Protocol (IP/TCP/UDP/ICMP), Destination IP/Network Mask, Destination Port, Action (Permit/Deny) and Click **Add**.

The supported RADIUS clients for ACL mode are Cisco, Juniper, and HP switches. If there are any unsupported clients listed in the Supported RADIUS client table then the ACL configuration will be disabled.

Control Access using Radius Return Attribute-Select this option to specify the return attributes you want sent to the Switch/WLC.

- Select the return attribute to send from the attribute list. Enter the value for the selected attribute and then click **Add**.
- You can specify multiple return attributes and values for this policy.

- To rearrange the order in which you want to send the return attributes, select the check box next to the attribute name and then click the up or down arrow.
- To delete an attribute, select the check box next to the attribute name then click Delete.

If both (user/policy) have the same attributes, preference will be given to User attribute values.

Add Session-Timeout attribute-Select this option to specify the action (Terminate the session or reauthenticate the session) taken upon on the expiration of session timeout.

7. Under Roles, specify:

- **Any role**-To apply the policy to all users.
- **Selected roles**-To apply this policy only to users who are mapped to roles in the Selected roles list. You must add roles to this list from the Available roles list.
- **Roles other than those selected below**-To apply this policy to all users except for those who map to the roles in the Selected roles list. You must add roles to this list from the Available roles list.

8. Click **Save Changes**.

VLAN change using CoA is not supported with Cisco Switches. It is recommended to use RADIUS disconnect for VLAN change.

Return Attributes Request Attributes Attribute Logging

Show policies that apply to:

A RADIUS return attributes policy specifies the return list attributes to send to an 802.1X network access device, such as which VLAN endpoints must use to access the network. If no policy applies, Open Port is the default action.

	Policies	ACL Settings	Attributes	Location Group	Interface	Applies to role
1.	Full Access Policy	ACL Rule=Protocol/tcp, Destination IP: 10.204.89.245, Destination Port: 443, Action: permit ACL Rule=Protocol/tcp, Destination IP: 10.204.89.245, Destination Port: 443, Action: deny	VLAN=80 Filter-Id=PERMIT-ALL in	Cisco Test Location	AUTO	ENG

Example configuration for parsing ACL rule name (HP, Cisco, and Juniper)

IPS ACL rule configuration	tcp 10.xx.xx.x 443 Permit
HP 2920 expansion	HP-nas-filter-rule=permit in tcp from any to 10.xx.xx.x 443
Cisco 3850 expansion	ip:inacl#100=permit tcp any host 10.xx.xx.xxx eq 443
Juniper - EX 2200 expansion	Juniper-Switching-Filter='Match Destination-ip 10.xx.xx.x Ip-protocol 6 Destination-port 443 Action allow'

Example configuration for parsing ACL name (HP, Cisco, and Juniper)

Vendors	Cisco	HP	Juniper
RADIUS VSA	filter-id	filter-id	filter-id

Vendors	Cisco	HP	Juniper
Example- RADIUS VSA value	<ACL-NAME>.in	<ACL-NAME>.in	ACL-Name

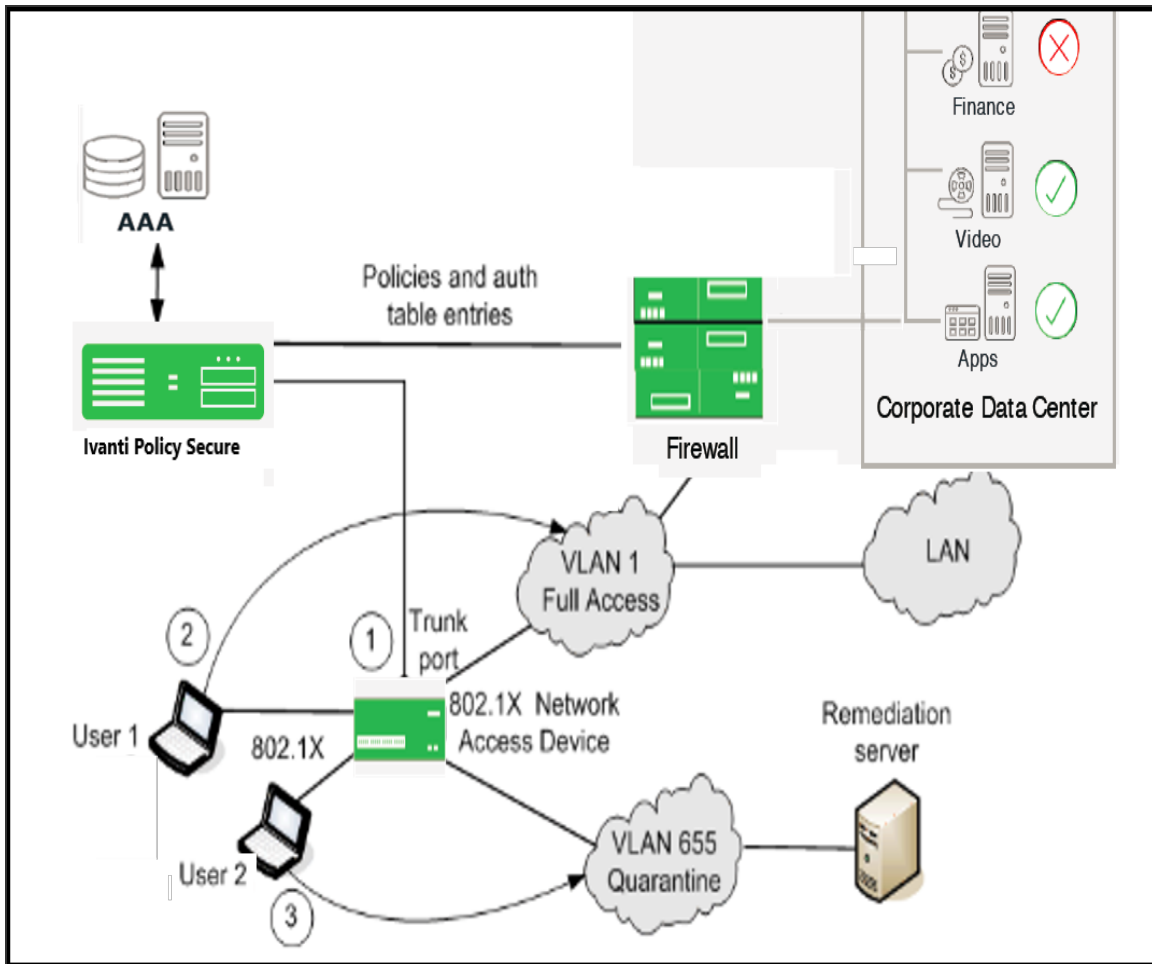

Example: RADIUS Attribute Policies

You can configure RADIUS attributes in the IPS to send return list attributes to an 802.1X network access device. For example, you can specify which VLAN the endpoint must use to access the network. You can also configure other functions on the network devices port based on the role assignment. For example, a particular Switch might let you use return attributes to configure QoS functions (bandwidth, priority, or both) on the device port based on the user role.

The example illustrates a RADIUS attribute policy to specify VLANs for endpoints, using the following steps:

- If you are using more than two VLANs, connect IPS internal interface to the trunk port on a VLAN-enabled switch that detects all the VLAN traffic.
- You can also configure a RADIUS attributes policy with the Automatic setting, which enables IPS to take advantage of VLAN tagging. When connected to a trunk port on a VLAN-enabled switch, IPS detects traffic from all VLANs.
- You can also configure routing on the network to enable endpoints to access IPS over the network. In this case, you must configure RADIUS attributes policies with the VLAN IDs you are using for endpoints, but you do not need to configure any VLAN ports on IPS.

The following figure illustrates an example of using a RADIUS attributes policy to specify VLANs for endpoints.

- If the user 1 is authenticated and the endpoint complies with Host Checker security policies, then the user is assigned a role on the Full Access VLAN that allows full network access and access to protected resources.
- If user 2 is authenticated but the endpoint does not comply with Host Checker security policies. The user is assigned a role on the Quarantine VLAN that only allows access to a remediation server.

Example: Configuring various RADIUS Return Attribute Policies

Configuring VLAN Assignment using RADIUS return Attribute Policy

This configuration describes how to send VLAN assignment to the Switch/WLC by returning RADIUS attributes.

1. Select **Ivanti Policy Secure > Network Access > RADIUS Return Attributes**.
2. Under Access Control Policy Settings, select Control the **Access > Control using VLAN ID**.
3. Specify a **VLAN ID**.

Configuring VLAN Assignment along with other RADIUS return Attributes Policies

This configuration describes how to send VLAN assignment and other attributes to the Switch/WLC by returning RADIUS attributes.

1. Select **Ivanti Policy Secure > Network Access > RADIUS Return Attributes**.
2. Under **Access Control Policy Settings**, select Control the **Access > Control using VLAN ID**.
3. Specify a VLAN ID.
4. Select **Control Access using Radius Return Attributes**.
5. Select the attribute you want to return from the Attribute list.
6. For Value, specify an attribute value.

Configuring Filter-ID using RADIUS Return Attribute Policy

This configuration describes how to send Filter-ID to switch/WLC by using the Filter-ID return attribute.

1. Select **Endpoint Policy > Network Access > RADIUS Return Attributes**.
2. Under Access Control Policy Settings, select Control Access using Radius Return Attributes.
3. Select **Filter-ID** from the Attribute list.
4. For value, specify the policy name.
5. Configure the filter on the NAD.

Configuring VLAN Assignment in a multi-vendor Switch Environment

This configuration describes how to send VLAN assignment in a multi-vendor switch environment that includes switch/WLC from different vendors. For example, you might have one type of switch that supports RADIUS tunnel attributes only, a second type of switch that supports the Filter-ID return attribute only, and a third type of switch that supports both.

1. Select **Endpoint Policy > Network Access > Location Group** and create a location group policy for each type of NAD.
2. Create a location group policy for switches that support RADIUS tunnel attributes only.
3. Create a second location group policy for switches that support the Filter-ID return attribute only.
4. Create a third location group policy for switches that support both RADIUS tunnel attributes and the Filter-ID return attribute.
5. Select **Endpoint Policy > Network Access > RADIUS Client**. Then, follow these steps to create a RADIUS client policy for each type of NAD and associate each RADIUS client policy with the appropriate location group.
6. Create a RADIUS client policy and specify a make/model for Make/Model that supports the RADIUS tunnel attributes. Associate this policy with the location group policy for switches that support RADIUS tunnel attributes only.
7. Create a second RADIUS client policy and specify a make/model that supports the Filter-ID return attribute. Associate this policy with the location group policy for switches that support the Filter-ID return attribute only.
8. Create a third RADIUS client policy and specify a make/model that supports the both RADIUS tunnel attributes and the Filter-ID return attribute. Associate this policy with the location group policy for switches that support both RADIUS tunnel attributes and the Filter-ID return attribute.
9. Select **Endpoint Policy > Network Access > RADIUS Attributes** and then follow these steps:
 - Create a RADIUS Attributes policy that specifies only the VLAN option and a value for VLAN ID. Associate this policy with the location group policy for switches that support RADIUS tunnel attributes only.
 - Create a second RADIUS Attributes policy that specifies only the Filter-ID option from the Attribute list and a policy name for Value. Associate this policy with the location group policy for switches that support the Filter-ID return attribute only.
 - Create a third RADIUS Attributes policy that specifies both the VLAN option and a value for VLAN ID, and the Filter-ID option with a policy name for Value. Associate this policy with the location group policy for switches that support both RADIUS tunnel attributes and the Filter-ID return attribute.

Configuring RADIUS Request Attribute Policies

RADIUS request attribute policies allows you to enforce the authentication requests based on information in the RADIUS packet. RADIUS request attribute policies consist of rules. Each rule consists of one attribute and some number of values. The type of value depends on the type of rule chosen. For example, if you select a rule with the User-Name attribute, you enter a string.

- RADIUS request attribute policy names must be unique.
 - Each request page includes guidance on what type of value is expected.
-

If you select a rule with the Login-IP-Host attribute, you enter an IP address and an optional netmask. The default netmask value is 255.255.255.255. The value of the attribute must fall within the specified IP address and netmask to pass the policy.

The RADIUS Access-Request attribute policy performs two tasks:

- Determines communication with the RADIUS client, indicating that the specified attributes must be sent in the Access-Request message.
- Parses the attribute-value pairs that are sent in the Access-Request message against the allow/deny rules you configure. The result of rules processing can be enforced in a realm restriction.

To configure a RADIUS Request attribute policy:

1. Select **Endpoint Policy > Network Access > RADIUS Attributes > Request Attributes** to display the configuration summary page.

2. Click **New** to display the policy configuration page.

Network Access > RADIUS Request Attributes > RADIUS Request Attribute Policy

RADIUS Request Attribute Policy

Use this policy to restrict the users with these RADIUS Request Attributes

▼ RADIUS Request Policy

* Policy Name: Label to reference this RADIUS Request Attribute Policy.

Description:

▼ Rule Settings

ARAP-Password To manage attributes, see the RADIUS Dictionary

<input type="checkbox"/>	Request Attribute	Value	Allow/Deny
<input type="checkbox"/>			
<input type="checkbox"/>			

3. Specify a policy name and description.

4. Under Rule Settings, select a RADIUS Access-Request attribute and click Add to display the rule configuration page.

Network Access > RADIUS Request Attributes > RADIUS Request Attribute Policy

RADIUS Request Attribute Policy

Use this policy to restrict the users with these RADIUS Request Attributes

▼ RADIUS Request Policy

* Policy Name: Label to reference this RADIUS Request Attribute Policy.

Description:

▼ Rule Settings

ARAP-Password To manage attributes, see the RADIUS Dictionary

<input type="checkbox"/> Request Attribute	Value	Allow/Deny

5. Complete the rule configuration as described below.

Settings	Guidelines
Add	Specify values or a pattern for rule matching. The system parses wildcards and value expressions as follows:
	String-An asterisk (*) matches multiple characters and a question mark (?) matches a single character.
	Integer-An asterisk (*) matches any value. You can use a hyphen to specify a range of values, for example 1-99 .
	Hexadecimal-An asterisk (*) matches any value.
	Click Add again to add more attribute values, as necessary. The result of adding multiple values is a comma-separated list.
Allow / Deny	Select Allow to permit access to matching sessions. Select Deny to deny access to matching sessions.

6. Save the rule configuration and return to the policy configuration page.

Network Access > RADIUS Request Attributes > RADIUS Request Attribute Policy

RADIUS Request Attribute Policy

Use this policy to restrict the users with these RADIUS Request Attributes

▼ RADIUS Request Policy

* Policy Name: Label to reference this RADIUS Request Attribute Policy.

Description:

▼ Rule Settings

ARAP-Password To manage attributes, see the RADIUS Dictionary

<input type="checkbox"/> Request Attribute	Value	Allow/Deny
<input type="checkbox"/> NAS-Port	30,34	Allow

Configuring a RADIUS Request Policy Realm Restriction

RADIUS request attribute policies can be assigned with a realm restriction. Any authentication request that comes from a realm with attribute policy requirements sends the RADIUS attributes specified in the policy, otherwise the authentication request is not granted. If multiple rules are configured in a policy, then all rules in the policy must pass otherwise the authentication fails.

If a user authentication fails based on the RADIUS request attribute policy, a user event log message is displayed. Debug logs allow the administrator to determine that a user met the policies, or indicate that the user failed a RADIUS return attribute policy.

To configure a RADIUS Request realm restriction:

1. Select **Endpoint Policy > Network Access > RADIUS Attributes > Request Attributes** to display the configuration summary page.
2. Click **New** to display the policy configuration page.
3. Complete the configuration as described in the following table.
4. Click **Save**.

User Realms > L2-Wired > Authentication Policy > RADIUS Request Policies

RADIUS Request Policies

General **Authentication Policy** Role Mapping

Source IP Browser Certificate Password Host Checker Limits **RADIUS Request Policies** SSO

Restrict the users based on the RADIUS request attributes received from the connecting NAS device. If none of these policies are set then all users will be allowed. By default, a user will be allowed if any one of the selected policies holds true. To configure these policies go to RADIUS Request Policies.

☒ Allow access to realm if any ONE of the selected policies are passed

Save Changes

Settings	Guidelines
Policy list	Use the Add and Remove buttons to create a policy list. The available policies are populated by the RADIUS request policies configured in the prior procedure.
Allow access to realm if any one of the selected policy is passed.	This option determines what happens when multiple policies match. Select this option to allow access to the realm if any of the matching policies allow access (Ignoring any matching deny policies). Do not select this option if you want to deny access if one of the matching policies deny access (Ignoring any matching allow policies).

Configuring RADIUS Attribute Logging

You can configure IPS to enable or disable authentication reporting for RADIUS authentication events. Using this feature you can obtain a granular record of authentication attempts using configurable and detailed authentication reports.

You can selectively choose events to record based on both successful and unsuccessful authentication attempts. If you select an attribute to be recorded and the value is not present in the authentication request/response, an entry is made in the debug log and in the RADIUS log. You can also specify accounting log messages.

The byte limit for log entries is 2048. If a message exceeds the byte limit the last value is trimmed and an entry is made in the debug and RADIUS logs.

To configure RADIUS attribute logging:

1. Select **Endpoint Policy > Network Access > RADIUS Attributes > Attribute Logging**.

Network Access > Radius Attribute Logging

Save Changes

2. Select Authentication Success Log Message and Authentication Reject Log Message.
3. Select the **Accounting Log Message** option to specify the accounting log messages.
4. Select **Available attributes** from the lists, and click Add to populate the Selected Attributes lists.
5. Click **Save Changes**.

- To include the RADIUS accounting messages in user access logs, select **System > Log/Monitoring > User Access > Settings and enable RADIUS Accounting Messages**.
 - The order of RADIUS attributes in the user access log is based on the order you select the attributes from the RADIUS attributes logging page.
-

Verifying the RADIUS Request Attribute Policy Configuration

When a user authentication fails because it did not meet the requirements specified in the RADIUS request attribute policy, a user event log message is displayed that includes information about which policies the user met or failed.

To display the User Access log:

1. Select **System Log/Monitoring**.
2. Click the **User Access** tab.
3. Click the **Log** tab.

Verifying the RADIUS Dictionary

IPS supports many specific network access devices (NAD) by using its built-in standard RADIUS and vendor-specific, proprietary dictionary files. You can upload new dictionaries to add new RADIUS clients. IPS uses the dictionary files to store lists of RADIUS attributes, parse authentication requests, and generate responses.

To upload a new RADIUS dictionary:

1. Select **Endpoint Policy > Network Access > RADIUS Dictionary** to display the preconfigured dictionaries and their associated vendors.

2. Click **New RADIUS** dictionary.

The screenshot shows a web interface for creating a new RADIUS dictionary. At the top, a breadcrumb trail reads 'Network Access > RADIUS Dictionary > New RADIUS Dictionary'. Below this is the title 'New RADIUS Dictionary' in green. A green heart icon is followed by 'RADIUS Dictionary'. The form contains two required fields: '* Name:' with a text input box and a tooltip 'Label to reference this RADIUS Dictionary.', and 'Description:' with a larger text area. Below these is the '* Dictionary:' section, which includes a blue 'Browse' button, the text 'No file chosen', and 'Dictionary file'. A note states 'Note: Save Changes will restart RADIUS service'. At the bottom is a blue 'Save Changes' button. A footnote at the very bottom says '* indicates required field'.

3. Enter a Name and optionally a description for the new dictionary.
4. Click **Browse** to search for the dictionary file (.dct) on a local or connected drive, then click **Save Changes**. The uploaded dictionary is displayed on the main RADIUS Dictionary page, and in the Make/Model list on the RADIUS Client page.
5. Click **Save Changes**.

- You can only remove dictionaries that are not associated with a vendor.
- You can download any dictionary from the list, including preinstalled dictionaries. You can modify the downloaded dictionary and then upload it as a new make/model.

Verifying RADIUS Vendor List

RADIUS server contains a file with the list of manufacturers for the access devices, which communicate with the RADIUS server.

To verify the vendor and the associated dictionary on the RADIUS Vendor page:

1. Select **Network Access > RADIUS Vendor**.
2. Click **New RADIUS Vendor**, enter the name and then select the imported dictionary.

Network Access > RADIUS Vendor > New RADIUS Vendor

New RADIUS Vendor

♥ RADIUS Vendor

* Name: Label to reference this RADIUS Dictionary.

Description:

* Dictionary: To manage dictionary, see the [RADIUS Dictionary](#)

Note: Save Changes will restart RADIUS service

[Save Changes](#)

* indicates required field

3. Click **Save Changes**.

Additional Configurations

Configuration Commands for Cisco Switch

The below example shows a sample configuration of 802.1X authentication on Cisco switch. Only sample commands are documented in this example. For more information, see Cisco documentation.

The configuration involves the following:

- Configuring IPS server as a RADIUS server in configuration mode.
- Configuring 802.1X on the switch port in configuration mode.

Configuring IPS server as a RADIUS server

The sample configuration below shows how to add IPS server as a RADIUS authentication and accounting server on Cisco switch.

You must execute the following commands in the CLI configuration mode.

```
--Execute this command to add IPS as a RADIUS server
    radius server <RADIUS SERVER NAME>
*Note* IPS listens to both 1812/1813 and 1645/1646 ports. Default is 1645
and 1646.
    address ipv4 <RADIUS SERVER IP> auth-port 1645 acct-port 1646
    key <SHARED-KEY>
--Execute these commands to create a RADIUS Server Group, and associate
your IPS appliances to the group.
    aaa group server radius <RADIUS-GROUP>
    server name <RADIUS SERVER NAME>
*Note* Repeat for every IPS Appliance.
--Execute these commands to turn on AAA
    aaa new-model
    aaa session-id common
    aaa authentication dot1x default group <RADIUS-GROUP>
    aaa authorization network default group <RADIUS-GROUP>
    aaa authorization auth-proxy default group <RADIUS-GROUP>
    aaa accounting send stop-record authentication failure
    aaa accounting identity default start-stop broadcast group <RADIUS-
GROUP>
    aaa accounting update newinfo
-- Execute this command to configure RADIUS CoA
    aaa server radius dynamic-author
    client <RADIUS SERVER IP> server-key <SHARED-KEY>
    auth-type all
    ignore session-key
    port 3799
*Note* Default is 1700
--Optional commands for DHCP snooping and IP device tracking for dACL or
filter id attributes
    ip device tracking
    ip dhcp snooping
    ip http server
    ip http secure-server
```

Configuring 802.1x and MAC Authentication

The below example shows a sample configuration of 802.1X and MAC Address authentication on Cisco switch interface. You must execute the following commands in CLI configuration mode.

```
interface GigabitEthernet1/0/24
```

```
switchport access vlan 60
switchport mode access
--Execute this command to trigger re-authentication from IPS
authentication periodic
authentication timer reauthenticate server
--Execute this command for configuring 802.1X
access-session port-control auto
dot1x pae authenticator
--Execute this command for configuring MAC BYPASS
mab
spanning-tree portfast
service-policy type control subscriber POLICY_Gi1/0/24
--POLICY_Gi1/0/24 is a policy map configuration. See the POLICY_MAP
configuration for more details.

--Specify the order of execution

authentication order mab dot1x
authentication priority dot1x mab
--Execute this command for viewing the status of the session on Cisco OS
version 15.x and above
Show access-session interface gi-X/Y/Z detail
--Execute this command for viewing the status of the session on Cisco OS
version 12.
Show authentication session interface gi-X/Y/Z detail
```

Configuration Commands: Juniper EX Series Switch

The below example shows a sample configuration of 802.1X authentication on Juniper EX switch.

The configuration involves the following:

- Configuring IPS server as a RADIUS server in edit mode.
- Configuring 802.1x on the switch port in edit mode.

Configuring IPS server as a RADIUS server

The sample configuration below shows how to add IPS server as a RADIUS authentication and accounting server on Juniper EX switch. You must execute the following commands in edit mode.

```
set access radius-server <RADIUS SERVER IP> secret <SHARED-KEY>
set access radius-server <RADIUS SERVER IP> source-address
10.204.88.30
--Execute this command for configuring RADIUS CoA
set access radius-server <RADIUS SERVER IP> dynamic-request-port 3799
--Execute this command to add IPS as a RADIUS server
```

```
set access profile 802.1X-access-profile authentication-order radius
set access profile 802.1X-access-profile accounting order radius
set access profile 802.1X-access-profile radius authentication-server
<RADIUS SERVER IP>
set access profile 802.1X-access-profile radius accounting-server
<RADIUS SERVER IP>
```

Configuring 802.1x on the Switch Port

The below example shows a sample configuration of 802.1X / MAC address authentication on Juniper EX switch interface. You must execute the following commands in edit mode.

```
--Execute this command for 802.1X
set protocols dot1x authenticator authentication-profile-name 802.1X-
access-profile
set protocols dot1x authenticator interface ge-0/0/0.0 supplicant
multiple
--Execute this command for configuring MAC BYPASS
set protocols dot1x authenticator interface ge-0/0/0.0 mac-radius
--Execute this command for viewing the status of the session
Show dot1x interface ge-X/Y/Z detail
```

RADIUS Dictionary Files

This section contains dictionary translations for parsing requests and generating responses. All transactions are composed of Attribute/Value Pairs. The value of each attribute is specified as one of these valid data types shown in table.

Data	Description
hexadecimal	Hexadecimal string
hex1, hex4	1- or 4-byte hexadecimal number
string	0-254 octets (includes null terminator)
stringnz	0-254 octets (without null terminator)
ipv6addr	16 octets in network byte order (per RFC-3162)
ipv6prefix	2-18 octets in network byte order (per RFC-3162)

Data	Description
ipv6interface	8 octets in network byte order (per RFC-3162)
ipaddr	4 octets in network byte order
ipaddr-pool	IP address selected from an IP address pool
ipxaddr-pool	IPX network number selected from an IPX address pool
integer	32-bit value in big endian order (high byte first)
int1, int4	1- or 4-byte decimal number (integer is equivalent to int4)
time	32-bit value in big endian order; seconds since 00:00:00 GMT, Jan. 1, 1970

All attribute names and value names in the supplied radius.dct dictionary are derived from the RADIUS specification by replacing all nonalphanumeric characters with dashes (-).

The following dictionary format provides a mechanism for including secondary dictionaries from the text of a primary dictionary. For example, only the attribute/value definitions that differ from the RADIUS specification need to be listed in a primary dictionary for a vendor specific implementation. Definitions for the attribute/values that are common to both are brought in by including the radius.dct dictionary anywhere within the vendor dictionary.

The following rules apply to the creation and use of dictionaries:

- All comments begin with a pound sign (#) in column 0 OR appear on an attribute or value line with <white space>#<white space> as the Mandatory delimiter between dictionary data and comment text. (This is a simple parser.)
- Include another dictionary file with an at sign (@). The (@) character must be in column 0.

- All attribute and attribute value names and numeric codes must be unique within a single dictionary. Conflicts between dictionaries are resolved according to the following rules:
 - Attributes and values have precedence over any that are parsed later, and parsing is depth first.
 - For example, to override a baseline attribute, create a file with that attribute in it, followed by an include of the baseline file. Because the baseline file is parsed later than the desired override, the baseline file is ignored.
 - When two secondary dictionary definitions of an attribute or value conflict, the earlier include takes precedence.
 - Other than include files, there are two meaningful line entry formats in a dictionary -one for attributes and one for attribute values.
 - `ATTRIBUTE_KEY ATTRIBUTE_NAME ATTRIBUTE_CODE DATA_TYPE FLAGS [COMMENT_
DELIMITER COMMENT_TEXT]`
 - `VALUE_KEY ATTRIBUTE_NAME VALUE_NAME VALUE_CODE [COMMENT_DELIMITER
COMMENT_TEXT]`
- The legend for the last column of an attribute entry should be:
 - 'c' indicates a SINGLE value attribute that is a candidate for inclusion in a user's checklist.
 - 'C' indicates a MULTI value attribute that is a candidate for inclusion in a user's checklist.
 - 'r' indicates a SINGLE value attribute that is a candidate for inclusion in a user's reply list.
 - 'R' indicates a MULTI valued attribute that is a candidate for inclusion in a user's reply list.
 - 'o','O' ordered attribute, some attributes (such as Reply-Message) might need to be presented in a particular order to make sense.

- The absence of {C,c,R,r} flags indicates an item that is neither a reply nor a check list item (such as State, Proxy-State).
 - All FLAG characters on a given attribute line must be clustered together to parse properly. No white space is allowed between individual characters.
-

Policy Enforcement using MAC Authentication

Overview

Media Access Control (MAC) authentication is used to authenticate devices based on their physical MAC addresses. Using MAC authentication IPS accepts the device MAC address as user credentials, matches it with the local database or LDAP server and then assigns the port connecting the device to a predetermined VLAN. MAC addresses can be easily spoofed so we recommend you to create separate VLANs or filters specifically for devices using MAC authentication. For example, you can create separate a special VLAN or separate filters for each of the device type such as printers, VOIP phones, and so on. You can also use Profiler for device validation and MAC authentication. For more information, see Profiler.

MAC based authentication is not as secure as agent access or agentless access authentication. MAC addresses are not generally guarded as secrets, so an attacker can spoof a MAC address and impersonate a device to gain network access. To reduce risk of an exploit, create a special VLAN for each device type.

Benefits of MAC authentication

The benefits of MAC authentication are:

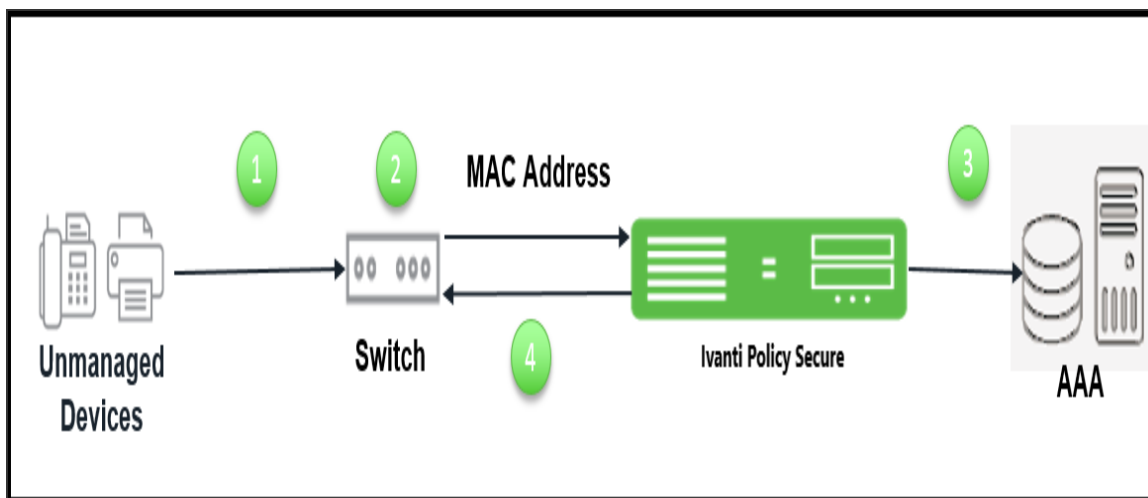

- IPS supports MAC authentication using both a local database and with LDAP servers.
- Supports authentication for unmanageable devices, such as printers, VOIP phones, and so on.
- Supports device validation and MAC authentication using Profiler.

Deployments using MAC Authentication

MAC address authentication is port-based security typically deployed at the edge of the network to enable secure access for devices, such as IP phones, printers, and network attached storage devices. The IPS MAC address authentication solution uses IPS 802.1x framework. When a device connects to a switch, the switch forwards the MAC address as the log in credential to IPS RADIUS server. Using MAC based authentication, the MAC address serves as both the username and the password. The RADIUS server consults the authentication server and sends back a RADIUS return attribute based on the authentication results.

Deployment of IPS using Local MAC Authentication Server

IPS supports MAC address authentication using a local Mac Authentication server. You can configure the IPS server to act as the authentication and policy server for MAC address authentication and optionally a separate directory/attribute server. You cannot use a RADIUS server with outer proxy authentication for MAC address authentication.

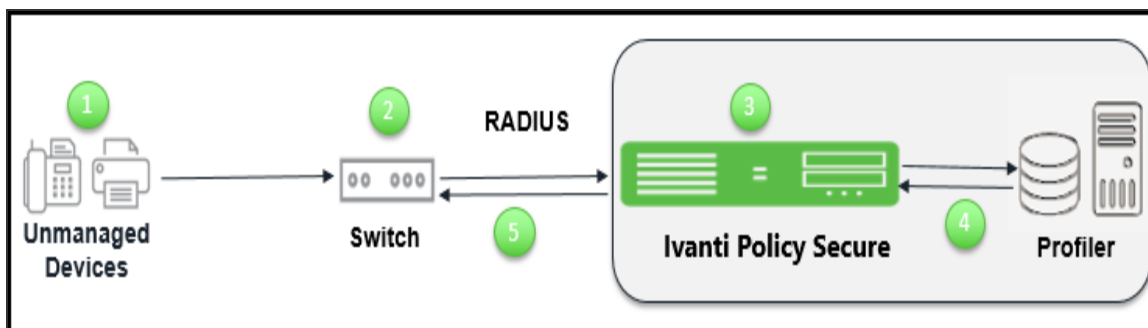

The authentication process is described below:

1. Unmanaged devices connect to network switch.
2. IPS accepts the device MAC address as username and password using MAC Authentication.
3. IPS matches the MAC address with the entries either in a local database or external database and then assigns a port connecting the device to a predetermined VLAN or filter id.
4. If the device MAC address is not found, then IPS places the device in a specified default VLAN.

Deployment of IPS using Profiler

IPS supports the device validation using Profiler. Profiler dynamically identifies and classifies endpoints across managed and unmanaged endpoint devices, so that access to network and resources can be controlled based on the type of the device.

The authentication process is described below:

1. Profiler discovers and classifies the endpoints on the network.
2. Unmanaged devices connect to network and the switch sends MAC RADIUS query.
3. IPS verifies the MAC address in Profiler database.
4. IPS then assigns role based on device attributes.
5. IPS assigns the switch port to appropriate VLAN or filter id.

For more information on Profiler, see *Ivanti Deployment Guide*.

Configuring MAC Authentication on IPS

To allow access for unmanageable devices, configure the necessary VLANs on your internal network to accommodate the different devices that you want to allow. On IPS, you assign devices to VLANs through the location groups that are added to RADIUS attributes policies.

Configuring the MAC Address Authentication Server

To support MAC authentication, add a MAC authentication server to IPS. You can either configure the MAC addresses directly on IPS or you can associate the MAC authentication server with an LDAP server.

To configure the MAC address authentication server:

- 1. Select **Authentication > Auth.Servers.**
- 2. Select **MAC Address Authentication** and click **New Server** to display the configuration page
MAC address authentication server configuration page.

Settings	Guidelines
Attributes	If you have selected LDAP servers in the configuration, save the configuration. After you have saved the configuration, the Attributes button is displayed. Click the Attributes button to display the LDAP server catalog, which you can use to select or add attributes to be retrieved from the LDAP servers.

Configuring the MAC Address Authentication Realm and Role Mapping Rules

The MAC address authentication framework uses a special realm called the MAC Address Authentication Realm. You need not configure a sign-in policy while using MAC address authentication realm. The MAC Address authentication realm uses any username credential that matches one of the common variants of a MAC address format (colon-separated, dash-separated, and the like) and sends it to the MAC authentication realm based on its format.

To configure the MAC Address authentication realm and role mapping rules:

- 1. Select **Endpoint Policy > MAC Address Realm**.
- 2. Click **New** to create a new configuration.

MAC Address Realms > New Authentication Realm

New Authentication Realm

* Name:

3. Complete the configuration. The following table summarizes the key settings.

Setting	Guideline
Name	Enter the name of the realm.
Description	Enter the description for identifying the realm.
Server	
Authentication server	Select the MAC Address authentication server configured.
User Directory/Attribute	Select the LDAP authentication server configured.
Accounting	Select the MAC Address authentication server configured.
Device attribute	Specify the server for device authorization. For profiler, select the name of the local profiler.
Dynamic Policy Evaluation	
Dynamic Policy Evaluation	Select this option to automatically or manually refresh the assigned roles of users by evaluating a realm's authentication policy, role-mappings, role restrictions, and resource policies.

4. Save the configuration. Upon saving the new realm, the system displays the role mapping rules page. Under Role Mapping tab, click **New Rule**. Role Mapping Rule page appears.
5. Select **Device Attribute** under **Rule based on** tab and click **Update**. Enter the name for the rule.
6. Select the relevant Attribute under Attributes tab for Role Mapping and enter an appropriate value.
7. Select an appropriate role from Available Roles and Click **Add** to Selected Roles.

8. Click **Save Changes** to save the configuration settings.

The screenshot shows the 'Role Mapping Rule' configuration page. At the top, the breadcrumb is 'MAC Address Realms > MAC_Realm > Role Mapping > Role Mapping Rule'. The title is 'Role Mapping Rule'. Below the title, there is a 'Rule based on:' dropdown set to 'Username' and an 'Update' button. A required field '* Name:' is present. A section titled '▼ Rule:if username...' contains a dropdown set to 'is' and a text input field. A note states: 'If more than one username should match, enter one username per line. You can use * wildcards.' Below this is a section titled '▼ then assign these roles'. It features two lists: 'Available Roles' (Guest, Guest Admin, OnboardRole, remed, Users) and 'Selected Roles' (none). Between the lists are 'Add ->' and 'Remove' buttons. A checkbox 'Stop processing rules when this rule matches' is checked. A link 'To manage roles, see the Roles configuration page.' is provided. At the bottom are 'Save Changes' and 'Save + New' buttons. A footnote '*Indicates required field' is at the very bottom.

Configuring User Roles for the MAC Address Authentication Realm

IPS access management framework evaluates authentication requests to match endpoints to roles. You must configure user roles for the various types of endpoints authenticated by the MAC address authentication framework.

To create a user role:

1. Select **Users > User Roles**.
2. Click **New Role**.
3. Complete the name and description configuration and then save the configuration.

4. Click **Agent** and deselect agent options and then save the configuration.

User Roles > New Role

Do not configure role restrictions for roles used with a MAC address authentication realm.

Configuring a Location Group

Location groups let you organize or logically group network access devices by associating the devices with specific sign-in policies. Sign-in policies provide a way to define and direct independent access control policies with the network. For example, you can create location group policies to logically group the network access devices in each building at a corporate campus. You can also use location group policies to specify a special realm for MAC address authentication.

To configure a location group:

1. Create a sign-in policy to associate with the location group.
2. Select **Endpoint Policy > Network Access > Location Group**.

The screenshot shows the 'New Location Group' configuration page. At the top, there is a breadcrumb trail: 'Network Access > Location Group > New Location Group'. Below this, the title 'New Location Group' is displayed in green. A green arrow icon points to the 'Location Group' label. The form contains several fields: a required field for 'Name' with the value 'MAC authentication' and a tooltip 'Label to reference this Location Group'; a 'Description' field; a required field for 'Sign-in Policy' with the value '*/guestadmin/' and a tooltip 'To manage policies, see the Sign-In Policies'; and a 'MAC Authentication Realm' dropdown menu with the value '(none)' and a tooltip 'To manage realm, see the MAC Address Realms'. A blue 'Save Changes' button is located at the bottom left. A note at the bottom left states '* indicates required field'.

3. On the New Location Group page, enter a name to label this location group and optionally a Description.
4. For Sign-in Policy, select the sign-in policy associate with the location group.
5. For controlling an unmanageable device using MAC address authentication, select a MAC Authentication Realm that you created from the list.
6. Click **Save Changes**.

Configuring RADIUS Client

A RADIUS client policy specifies the information required for unmanaged devices to connect as a RADIUS client of the IPS.

To configure a RADIUS client:

1. Select **Endpoint Policy > Network Access > RADIUS Client**.
2. Click **New RADIUS Client**.

♥ RADIUS Client

Cisco WLC 10.204.88.244 successfully updated.

* Name: Cisco WLC 10.204.88.244 Label to reference this RADIUS Client.

Description:

* IP Address: 10.204.88.244 IP Address of this RADIUS Client.

* IP Address Range: 1 Number of IP Addresses for this RADIUS Client

* Shared Secret: ***** RADIUS shared secret

Key Wrap ☒ Key Wrap (Support for RFC 6218)

* Key Wrap Format: ASCII Key Wrap Format

* Key Encryption Key(KEK): ***** Key Encryption Key(KEK), size should be 16 bytes

* Message Authentication Code Key(MACK): ***** Message Authentication Code key (MACK), size should be 16 bytes to 64 bytes

* Make/Model: Airespace To manage make/model, see the [RADIUS Vendor](#)

* Location Group: Default To manage groups, see the [Location Group](#)

♥ Dynamic Authorization Support

Support Disconnect Messages ☒ Disconnect Message Support

3. On the RADIUS Client page, enter a name to label the RADIUS client. You can assign any name to a RADIUS client entry, use the device's SSID or IPv4 address to avoid confusion.
4. Enter a purpose or description of the configuration so that other users are aware of it.
5. Enter the IP address of the NAD.
6. (Optional) For **IP Address Range**, enter the number of IP addresses in the IP address range for the switch/WLC, starting with the address you specified for IP Address. You can specify a range up to a maximum of 32,768 addresses.

7. For **Shared Secret**, enter the RADIUS shared secret. A RADIUS shared secret is a case-sensitive password used to validate communications between IPS and NAD. IPS supports shared secrets of up to 127 alphanumeric characters, including spaces and the following special characters:
~!@#\$%^&*()_+|\=-'{}[]:"';<>?/.,
8. For **Make/Model**, select the make and model of the NAD. The make/model selection tells IPS which dictionary of RADIUS attributes to use when communicating with this client.
9. For **Location Group**, select the location group to use with this NAD.
10. Under **Dynamic Authorization support**, Select the **Support Disconnect Messages** check box to send disconnect messages to supplicants if access is no longer authorized. If this check box is selected, a disconnect request is sent to the NAD any time a session is deleted. IPS can also send disconnect messages upon a role event that includes a VLAN change or a change in RADIUS attributes.
11. Select **Support CoA Messages** to enable CoA messages and disconnect messages support for the client.
12. (Optional) Enter a new **Dynamic Authorization Port** (Default port is 3799). The default port might vary depending on the manufacturer. NAD listens to UDP port to receive RADIUS CoA messages from IPS.
13. Click **Save Changes**.

MAC address authentication must be enabled on the switch port. See [Configuring 802.1x](#) and [MAC Authentication](#) on the Switch Port for switch configuration.

Configuring RADIUS Attributes

This configuration describes the configuration information for RADIUS return attributes policy that is applied on switch, request attribute policy, which can be used along with sign-in policies for realm selection, policy realm restrictions, and authentication/accounting reporting for RADIUS authentication events.

This configuration describes how to send VLAN assignment and other attributes to the switch/WLC by returning RADIUS attributes.

1. Select **Endpoint Policy > Network Access > RADIUS Attributes**, and then select VLAN.
2. Specify a VLAN ID.

3. Select Return Attribute.
4. Select the attribute you want to return from the Attribute list.
5. For Value, specify an attribute value.

IP Address Pools

In current implementation, the IPS supports only static IP address assignment. From 9.1R13, IPS also allows the admins to assign IP addresses dynamically for the users or nodes from IP address pools.

When the RADIUS authentication succeeds, if the pool name is configured in the Framed-IP-Address return attribute, then the available IP address is assigned to the user from the corresponding IP address pool. When the user session ends (on receiving acct-stop or admin deletes the user session), the assigned IP address is released back to the pool.

In order to release the IP address when a user is deleted from the active user page, it is necessary to have received an "accounting start" request after authentication request by the user/node.

IP address pools are not supported for dot1x and native dot1x use cases.

Configuring IP Address Pool

To configure the IP address pools, use the following procedure:

1. Navigate to **Endpoint Policy > Network Access > IP Address Pools**. The page lists the existing IP address pools. Click **New IP Address Pool...** to add a new address pool.

Network Access > IP Address Pools

IP Address Pools

RADIUS Dictionary

RADIUS Vendor

Location Group

RADIUS Client

IP Address Pools

3.
 1. To configure IP address pools for System Local Users, use the following procedure:
 - For System Local Users, under **Custom Attributes**, select **Framed-IP-Address**. Then select **IP Address Pool** as the type and select the name of the IP address pool to add to the attribute list.

The screenshot shows a web interface for configuring system attributes. A modal dialog titled "Framed-IP-Address" is open, allowing configuration of a new attribute. The dialog has two dropdown menus: "Framed-IP-Address Type" (set to "IP Address Pool") and "Value" (set to "IP Pool1"). An "OK" button is at the bottom of the dialog. In the background, the "Custom Attributes" section is visible, featuring a table with columns "Attribute" and "Value". The table contains three entries: "Framed-IP-Address" (with an empty value field and an "Add" button), "ACL-Name" (with value "asdf"), and "H3C-Product-ID" (with value "12345"). There are also "Delete", "Up", and "Down" buttons above the table, and a "Save Changes" button at the bottom left of the background interface.

Attribute	Value
Framed-IP-Address	
ACL-Name	asdf
H3C-Product-ID	12345

- (Mandatory) If Radius Return Attributes policy is configured, then under **Access Control Policy Settings** do one of the following:
 - Map the **Framed-IP-Address** attribute to the auth server catalog attribute.
 - Select **Framed-IP-Address**. Then select **IP Address Pool** as the type and select the name of the IP address pool to add to the attribute list.

The screenshot displays the 'Access Control Policy Settings' configuration page. A modal dialog titled 'Framed-IP-Address' is open, showing 'Framed-IP-Address Type' set to 'IP Address Pool' and 'Value' set to 'IP Pool1'. The main page has 'Control the Access' selected, with 'Control access using Radius Return Attributes' checked. Below this is a table for mapping attributes.

Return Attribute	Radius Auth Server Attribute Value	Auth Server Catalog Attribute Value	Value
Framed-IP-Address	-none-	-none-	

Buttons for 'Delete', 'Up', and 'Down' are located above the table. An 'Add' button is next to the 'Value' column. At the bottom, there is an option to 'Add Session-Timeout attribute'.

4. To configure IP address pools associated with Radius Client, use the following procedure:
- For Radius Clients, select the IP address pool from the list.

Network Access > RADIUS Client > New RADIUS Client

New RADIUS Client

▼ RADIUS Client

* Name: Label to reference this RADIUS Client.

Description:

* IP Address: IP Address of this RADIUS Client.

* IP Address Range: Number of IP Addresses for this RADIUS Client

* Shared Secret: RADIUS shared secret

* Make/Model: - Standard Radius - ▼ To manage make/model, see the [RADIUS Vendor](#)

Policy Enforcement using SNMP/SSH

Overview

IPS supports device visibility and policy enforcement on switches using SNMP as an alternative to 802.1X. Using SNMP enforcement, you can easily deploy and achieve comprehensive compliance and role based access.

Benefits of SNMP Enforcement

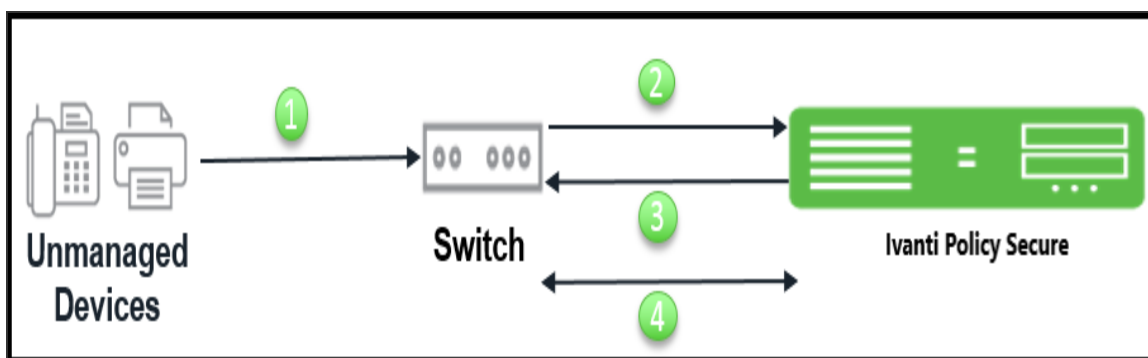

The following are the benefits of SNMP enforcement:

- Supports SNMP enforcement for MAC based authentication and role assignment.
- Supports network visibility using SNMP v1/v2/v3.
- The endpoints are discovered through SNMP traps (Linkup/Down, MAC notification, and Port security).
- Supports easy NAC deployment with SNMP enforcement based on compliance and role-based access.
- Supports Non-802.1X compliance endpoints.
- Supports SNMP discovery for L2/L3 switches.
- Supports session after SNMP MAC authentication.
- Supports hybrid deployment- 802.1X for wireless network and SNMP for wired network.

Policy Enforcement Using Simple Network Management Protocol/SSH

Policy Enforcement using SNMP for Unmanaged Devices

To deploy policy enforcement using SNMP for unmanaged devices, add the switch as an SNMP Agent and the IPS device as an SNMP server in the switch and then configure the SNMP Enforcement Policies in IPS.

The workflow for the SNMP policy enforcement using *linkup/MAC address Notification traps* is described below:

1. Unmanaged corporate devices such as phones, printers, and cameras connect to SNMP switch. The SNMP switch is configured for linkup/MAC address Notification trap. The SNMP switch generates the SNMP trap. See the Appendix section for switch configuration.
2. IPS learns or receives the MAC address.
3. IPS performs the MAC authentication and sets the VLAN/ACL based on the role assigned using SNMP.
4. When the user disconnects the device from the switch by plugging out the cable, IPS receives an SNMP trap and it deletes the session from the IPS server and sets the switch port to the default VLAN/ACL.

The workflow for the SNMP policy enforcement using *port-security trap* is described below:

1. Unmanaged corporate devices such as phones, printers, and cameras connect to SNMP switch. The SNMP switch is configured for port-security trap. A dummy static MAC address is configured on the port. Since machine's MAC address does not match with the configured dummy mac address, it generates a security violation and a port security trap is sent to IPS. See the Appendix section for switch configuration.
2. IPS learns or receives the MAC address.
3. IPS performs the MAC authentication and the dummy MAC address configured on the interface is replaced with the endpoint MAC address thus authorizing the endpoint on the switch and sets the VLAN based on the role assigned.
4. When the user disconnects the device from the switch by plugging out the cable, the session is not deleted from the IPS. However, the session is deleted only after the session timeout.

Policy Enforcement using SNMP for Managed Devices

To deploy policy enforcement using SNMP for managed devices, add the switch as an SNMP Agent and the IPS device as an SNMP server in the switch and then configure the SNMP Enforcement Policies in IPS.

The workflow for the SNMP policy enforcement using *link-up/MAC address Notification traps* is described below:

1. Managed corporate client (Ivanti Secure Access Client is installed) such as Windows/MAC OSX machine connects to SNMP switch port. The SNMP switch is configured for link-up/MAC address Notification trap. The SNMP switch generates the SNMP trap. See Appendix section for switch configuration.
2. IPS learns or receives the MAC address.
3. IPS performs the MAC authentication and sets the VLAN/ACL based on the role assigned using SNMP.
4. The user connects to IPS using Ivanti Secure Access Client. Host checker evaluates the compliance status of machine. If machine is compliant with Host Checker policy.
5. IPS sets the VLAN/ACL configured for compliant role using SNMP and if machine is non-compliant with Host Checker policy then IPS sets the VLAN/ACL configured for non-compliant role using SNMP.
6. When the user disconnects the Ivanti Secure Access Client. IPS reevaluates the role and sets the VLAN/ACL based on the role assigned.

7. When the user disconnects the endpoint from the switch by plugging out the cable, session from the IPS server is deleted and the switch port is set to the default VLAN/ACL.

The workflow for the SNMP policy enforcement using *port-security trap* is described below:

1. Managed corporate client (Ivanti Secure Access Client is installed) such as Windows/MAC OSX machine connects to SNMP switch port.
The SNMP switch need to be configured for port-security trap. A dummy static MAC address is configured on the port. Since the machine's MAC address does not match with the configured dummy mac address, it generates a security violation and a port security trap is sent to IPS.
2. IPS learns or receives the MAC address.
3. IPS performs the MAC authentication and the dummy MAC address configured on the interface is replaced with the endpoint MAC address thus authorizing the endpoint on the switch and sets the VLAN based on the role assigned.
4. When the user disconnects the device from the switch by plugging out cable, the session is not deleted from the IPS. However, the session is deleted only after the session timeout.
5. IPS sets the VLAN configured for compliant role using SNMP and if machine is non-compliant with Host Checker policy then IPS sets the VLAN configured for non-compliant role using SNMP.
6. When the user disconnects the Ivanti Secure Access Client. IPS reevaluates the role and sets the VLAN based on the role assigned.
7. When the user disconnects the device from the switch by plugging out the cable, the session is not deleted from the IPS. However, the session is deleted only after the session timeout.

- If the SNMP switch supports MAC Notification traps (MAC added notification trap), you must enable the traps in addition to the Link Up / Link Down traps.
 - If Port Security traps are enabled, LinkUp/LinkDown or MAC Added Notification traps should not be enabled.
 - IPS does not support MAC removed notifications trap. It tracks the session / MAC address associated with a particular interface and removes it once a link down trap is received.
 - MAC notification traps are supported only for Cisco and HP switches.
 - SNMP Enforcement using ACL is not supported using Port-Security traps.
-

Configuring SNMP Policy Enforcement using VLAN (Cisco, HP)

This section covers the configuration for SNMP policy enforcement. SNMP based policy enforcement is applied to endpoints running Ivanti Secure Access Client, and to clientless endpoints where the MAC address is discovered through SNMP. For endpoints running Ivanti Secure Access Client, role assignment is based on compliance; for clientless endpoints, role assignment is based on MAC address.

Configuring a MAC address Authentication Server

A MAC address authentication server defines how endpoints are authorized using the MAC address. You can choose to allow or deny a MAC address or use wildcards to allow or deny groups of MAC addresses.

To configure a MAC address authentication server:

1. Select **Authentication > Auth Server**.
2. Select **MAC Address Authentication** and click **New Server** to display the MAC Address Authentication Server configuration page as shown in figure.

Auth Servers > MACAuthServer

MACAuthServer

Settings Users

Name: MACAuthServer Label to reference this authentication.

MAC Addresses

Maximum 500 addresses

Delete [Up Arrow] [Down Arrow]

MAC Address	Action	Attributes	
	Allow		Add
00:11:85:3b:8c:66	Allow		

Example MAC Address:
00:11:85:3b:8c:66
00:ff:ff:ff:ff:ff
Example Attribute:
attribute1=value1;attribute2=value2;
(for attributes: alphanumeric or '-' or '_' characters only)
The Allow & Attributes action accepts the defined MAC Address expression and looks it up in the optional LDAP Server(s) below for authorization attributes.

Optional LDAP Servers

Available LDAP Servers: (none) Add -> Remove

Selected LDAP Servers: (none) [Up Arrow] [Down Arrow]

To manage servers, see the [Server](#) configuration page.

Server Catalog

Attributes...

The attributes catalog should be used for both attributes defined in the MAC Addresses Table and the optional LDAP Servers.

Save Changes Reset

* indicates required field

3. On the MAC address authentication server configuration page:

- For Name, enter a name to label this MAC address authentication server.
- Under MAC Addresses, enter the MAC address(es) to whitelist.
- Select an action to take when the MAC address matches:
 - **Allow**-Signal successful authentication.
 - **Deny**-Signal unsuccessful authentication.
 - **Allow and Attributes**-Typically, a match terminates the search. If you select Allow and Attributes, the search is not terminated; instead, the system searches the LDAP servers for a match in order to retrieve the LDAP authorization attributes.
- Specify a name-value pair to associate the MAC address with a particular group or organization.
- Under Optional LDAP servers, Use the **Add** and **Remove** selector buttons to add LDAP servers to the list of selected servers. Use the up and down buttons to order the list. The order in which the LDAP servers are listed is important.
- Under Server Catalog, Click the **Attributes** button to display the LDAP server catalog, which you can use to select or add attributes to be retrieved from the LDAP servers.

4. Click **Save Changes** to save the configuration.

Configuring a MAC address Authentication Realm and Role Mapping

A MAC address authentication realm uses a MAC address authentication server and role mapping rules to sort MAC address authentication requests into roles.

To configure a MAC address authentication realm:

1. Select **Endpoint Policy > MAC Address Realms**.
2. Click **New** to display the MAC Address Realm configuration page.

MAC Address Realms > MAC_Realm > General

General

Authentication Policy

Role Mapping

Name: Label to reference this realm

Description:

☐ When editing, start on the Role Mapping page

▼ Servers

Specify the servers to use for authentication and authorization. To create or manage servers, see the [Servers](#) page.

Authentication: Specify the server to use for authenticating users.

User Directory/Attribute: Specify the server to use for authorization.

Accounting: Specify the server to use for Radius accounting.

Device Attributes: Specify the server to use for device authorization.

Device Check Interval: minutes Specify the interval to check device attributes server.disable=0, min=10, max=10000 minutes

▼ Dynamic policy evaluation

☐ Enable dynamic policy evaluation

▼ Other Settings

Authentication Policy: No restrictions

Role Mapping: 1 Rule

[Save Changes](#)

3. On the MAC address realm configuration page:

- For Name, enter a name to label this MAC address realm.
- (Optional) For description, enter a description.
- For Authentication Server, select the MAC address authentication server configured earlier.
- For User Directory/Attribute Server, select "Same as above".
- For accounting, select the authentication server.
- For device attribute, select the server for device authorization. For profiler, select the name of the local profiler.
- Specify the device check interval in minutes.
- Select the **Enable dynamic policy evaluation** to automatically or manually refresh the assigned roles of users by evaluating a realm's authentication policy, role-mappings, role restrictions, and resource policies.

4. Click **Save Changes** to save the configuration.

Role mapping rules define how endpoints are assigned to roles.

To configure the role mapping rules for your MAC Address Realm:

1. Click the **Role Mapping** tab to display the role mapping configuration page for the realm.
2. Click **New** to display the MAC Address Realm configuration page.

- On the role mapping configuration page, click **New Rule** to display the role mapping rule configuration page.

MAC Address Realms > IMAC_Realm > Role Mapping > Role Mapping Rule

Role Mapping Rule

Rule based on: Username

* Name:

♥ Rule:if username...

is If more than one username should match, enter one username per line. You can use * wildcards.

Selected Roles: (none)

☐ Stop processing rules when this rule matches

To manage roles, see the [Roles configuration page](#).

*Indicates required field

- (Optional) For Name, enter a name to label this role mapping rule.
 - Select the rule from the Rule based list and provide the appropriate details.
 - Select the appropriate role and click **Add**.
- Click **Save Changes** to save the configuration.

Configuring a Location Group

A location group enables association of a sign-in policy and MAC address realm for network access policy enforcement.

To configure a location group:

1. Select **Endpoint Policy > Network Access > Location Group**.
2. Click **New Location Group** to display the Location Group configuration page.

Network Access > Location Group > New Location Group

New Location Group

▼ Location Group

* Name: Label to reference this Location Group.

Description:

* Sign-in Policy: To manage policies, see the [Sign-In Policies](#)

MAC Authentication Realm: To manage realm, see the [MAC Address Realms](#)

[Save Changes](#)

* indicates required field

3. On the location group configuration page:
 - Enter a name or label to describe the location group.
 - Enter a description.
 - Select the default sign-in policy as it is not applicable for SNMP enforcement. For example, default */ sign-in policy.
 - Select the MAC authentication realm which was configured earlier.
4. Click **Save Changes** to save the configuration.

Configuring SNMP Devices

You can add an SNMP device manually through SNMP device configuration or automatically discover SNMP devices through SNMP Device Discovery configuration.

Manual Addition of SNMP Devices

You can manually add SNMP devices from IPS. This section describes the SNMP device configuration for switches with different versions.

- Configuring devices with SNMP v1/v2c
- Configuring devices with SNMP v3

Configuring Devices with SNMP v1/v2c

To configure the device with SNMP v1/v2c:

1. Select **Endpoint Policy > Network Access > Network Infrastructure Device** and click **New Network** Infrastructure Device.
2. Enter a name to label this SNMP device.
3. For Description, enter a description. (Optional)
4. Enter the IP address of the SNMP device. You must enter a single IP address, not an IP address range or subnet.
5. Select the device vendor. SNMP VLAN enforcement check box will appear only for vendors who support SNMP enforcement. VLAN enforcement is supported only for HP and Cisco switches.
6. Under Enforcement, enable the **VLAN Enforcement** checkbox for using the device for SNMP enforcement using VLAN.
For Profiler, you must disable SNMP enforcement; the **Location Group, Default VLAN, Write Community** and **Trap Community String** fields are not applicable for profiling. A device so added is not used for enforcement.
 - For Location Group, select the location group configured earlier. Only location groups which have MAC Address Realms associated will be available for selection.
 - For Default VLAN, enter the VLAN to be provisioned when the SNMP user session is deleted or no endpoint is connected.
7. Under SNMP Settings, select **SNMP version v1/v2c**.
8. To use different credentials for write and trap community strings, disable the "Use same credentials for write and trap operations" check box.
9. Enter the community string(s) for the Read community.

10. Click **Save Changes** to save the configuration.

Network Access > Network Infrastructure Device > New Network Infrastructure Device

New Network Infrastructure Device

*Name: Label to reference this Device.

Description:

*IP Address: IP Address of this Device.

*Vendor: Device Vendor.

▼ Enforcement

ACL and/or VLAN will be used as an enforcement attribute to provision the policy for the endpoint. VLAN Enforcement is supported only for HP and Cisco.

Enforcement is supported only for Wired Switches.

ACL Enforcement ☐ VLAN Enforcement ☒

*Location Group: Only groups which are associated with a MAC Address realm appear here. To manage groups, see the [Location Group](#)

*Default VLAN: To set the device interface to default VLAN specified value when there is no ROLE assigned. This is mainly used when a SNMP session is deleted.

Same credentials for Write and Trap user ☒

*Read Community String:

Save Changes

Configuring Devices with SNMP v3

To configure the switch with SNMP v3:

1. Select **Endpoint Policy > Network Access > Network Infrastructure Device**.
2. Click **New Infrastructure Device**.
3. Enter a name to label this SNMP device.
4. For Description, enter a description. (Optional)
5. Enter the IP address of the SNMP device. You must enter a single IP address, not an IP address range or subnet.

6. Select the device vendor. SNMP VLAN enforcement check box will appear only for vendors who support SNMP enforcement. VLAN enforcement is supported only for HP and Cisco switches.
7. Under Enforcement, enable the **VLAN Enforcement** checkbox for using the device for SNMP enforcement using VLAN.
For Profiler, you must disable SNMP enforcement; the **Location Group, Default VLAN, Write Community and Trap Community String** fields are not applicable for profiling. A device so added is not used for enforcement.
 - For Location Group, select the location group configured earlier. Only location groups which have MAC Address Realms associated will be available for selection.
 - For Default VLAN, enter the VLAN to be provisioned when the SNMP user session is deleted or no endpoint is connected.
8. Under SNMP Settings, select **SNMP version v3** and define the SNMP switch settings:
9. Enter the Read Username, select the Read Security Level and Auth Protocol, and enter the Auth Password.
10. To use different credentials for write and trap community strings, disable the "Use same credentials for write and trap operations" check box.
11. Click **Save Changes** to save the configuration.

Network Access > Network Infrastructure Device > New Network Infrastructure Device

If you unplug a cable from an interface, the associated session would be deleted only if link down traps are enabled. If the port security traps are configured on the device, unplugging of the cable does not cause session deletion.

Auto Discovery of SNMP Devices

IPS provides an optional SNMP Device Discovery option. You can specify a range of IP addresses and other details needed for SNMP configuration to perform discovery of SNMP enabled devices.

IPS discovers all SNMP enabled L2 or L3 devices. SNMP enabled devices, which are not supported are listed as unsupported and cannot be added to the SNMP devices page.

To discover SNMP enabled devices:

1. Select **Endpoint Policy > Network Access > Network Infrastructure Device > Discovery.**

Network Access > SNMP Device Discovery > SNMP Device Discovery

SNMP Device Discovery

RADIUS Dictionary | RADIUS Vendor | Location Group | RADIUS Client | RADIUS Attributes | **SNMP Device** | SNMP Enforcement Policies

Configuration | **Discovery**

Atleast one of v2 or v3 settings need to be configured for enabling SNMP Discovery.

*IP address/range: IP address or range of IP addresses in CIDR format.

▼ **SNMP V2 Settings**

* Community string:

▼ **SNMP V3 Settings**

*User name:

Authentication protocol: Authentication Password:

Privacy protocol: Privacy Password:

Discover

	Name	IP Address	SNMP Version	Device Details	SNMP Enforcement	Location Group	Default Vlan
<input type="checkbox"/>	1 <input type="text" value="10.204.88.16"/>	10.204.88.16	V2	Vendor: CISCO Name: Profiler3750 Descr: Cisco IOS Software, C3750 Software (C3750-IPSERV) Location: Bangalore	<input checked="" type="checkbox"/>	initialSetup_snmp	<input type="text" value="123"/>

Add Device

2. On the SNMP device discovery configuration page:

- For IP Address Range, enter a range of IP addresses in CIDR format (for example, 10.204.88.0/28) to discover SNMP devices.
- To discover SNMP v1/v2c devices, enter the community string to use with SNMP v1/v2c device.
- To discover SNMP v3 devices, enter the user name to use with SNMP v3 devices. Enter the Authentication protocol, Authentication password, Privacy protocol and Privacy password for SNMP v3 devices.
- Click **Discover** to start the discovery process.

Once the devices are discovered, you must complete the following configuration for SNMP enforcement on each device:

1. Choose a location group from the dropdown list.
2. You can enable the SNMP VLAN enforcement for the supported switches (HP/Cisco).
3. Specify a default VLAN.
4. Select the devices to be added and click **Add Device**.
5. Click **Save Changes**.

The SNMP enforcement option is disabled for the Switches, which don't support SNMP enforcement.

Network Access > SNMP Device Discovery > SNMP Device Discovery

SNMP Device Discovery

Authentication protocol: Authentication Password:

Privacy protocol: Privacy Password:

Discover

	Name	IP Address	SNMP Version	Device Details	SNMP Enforcement	Location Group	Default Vlan	
<input type="checkbox"/>	1	<input type="text" value="10.204.88.16"/>	10.204.88.16	V2	Vendor: CISCO Name: Profiler3750 Descr: Cisco IOS Software, C3750 Software (C3750-IPSERV) Location: Bangalore	<input checked="" type="checkbox"/>	<input type="text" value="initialSetup_snmp"/>	<input type="text" value="123"/>

Add Device

- Discovery of SNMP-enabled devices applies only to L2 and L3 devices which support Bridge MIB configuration.
 - Enable the SNMP Enforcement checkbox for using the device for SNMP enforcement and then define the location group and the default VLAN. For Profiler, you must disable SNMP enforcement; the Location Group, Default VLAN fields are not applicable for profiling.
 - Admin can modify the added SNMP client to enable the ACL enforcement if required. See [Adding SNMP Client](#)
-

Verifying the status of SNMP Devices

You can view the SNMP device status from the SNMP Device page. You can view details such as device name, device location, device description, device contact information, SNMP version, IP Address, model, location group, default VLAN, default ACL, and the current status of the added device.

To view the status of SNMP devices:

1. Select **Endpoint Policy > Network Access > Network Infrastructure Device**.
2. Click **Configuration**.

Network Access > Network Infrastructure Device > Network Infrastructure Device Configuration

ACL: To manage ACLs, see the [ACL](#). If the ACL is directly configured on the switch, select '- Custom -' option.

Custom ACL: Specify the ACL which is directly configured on the switch.

▼ Roles

☐ Policy applies to ALL roles

☒ Policy applies to SELECTED roles

☐ Policy applies to all roles OTHER THAN those selected below

Available roles:

Selected roles:

3. On the SNMP policy configuration page:

- Enter a label for the SNMP enforcement policy.
- Enter a description for the SNMP policy.
- For VLAN, specify the VLAN to assign.
- Choose a location group from the dropdown menu.
- Under Roles, select Policy Applies to Selected Role; choose a role from the Available Roles and click Add to add it to the Selected Roles list.

4. Click **Save Changes** to save the configuration.

Configuring SNMP Policy Enforcement through Templates using ACL/VLAN

Policy enforcement using ACLs is achieved through both SNMP and SSH. The SNMP traps are received through SNMP and ACL enforcement is done using CLI (SSH).

Template based Policy enforcement using ACL/VLAN as enforcement attribute is achieved through a combination of SNMP and SSH protocols. SNMP protocol is used to receive the traps and ACL/VLAN enforcement is performed using CLI via SSH protocol.

Pre-requisites

- The user must be logged in with highest privilege level for ACL/VLAN enforcement using SSH.
- ACLs should be configured either manually on the Switch or pushed from 182 through ACL creation.
- Default templates are available for Cisco, Juniper and HP. For other Switch models/vendors the admin can create new template. See [Creating Template or using Existing Template](#).
- Enable SNMP diagnostic logging to capture the CLIs sent to the Switch.

Creating Template or using Existing Template

Template is required to specify the CLI format for each vendor. Admin can upload/download the templates which will be in pre-defined format. Using the template, CLIs are formed to enforce the ACL/VLAN on to the interface.

To view and add the templates:

1. Select **Endpoint Policy > Network Access > Network Infrastructure Device > Templates**.

Cisco, Juniper, HP, HP 3com, Dell, Alcatel-Lucent, Arista and Huawei switch templates are available by default.

New Template... Delete... Restore Factory Default...				
10 records per page			Search: <input type="text"/>	
	Name	File Name	Vendor	Device Type
1	cisco-switch-l2-enforcer.tmpl Template for SNMP policy enforcement with Cisco switches	cisco-switch-l2-enforcer.tmpl	Cisco Systems	Switch
2	hp-switch-l2-enforcer.tmpl Template for SNMP policy enforcement with HP Procurve switches	hp-switch-l2-enforcer.tmpl	HP Procurve	Switch
3	dell-switch-l2-enforcer.tmpl Template for SNMP policy enforcement with Dell NXXXX series switches	dell-switch-l2-enforcer.tmpl	Dell NXXXX Series	Switch

6	arista-switch-l2-enforcer.tmpl Template for SNMP policy enforcement with Arista Networks switches	arista-switch-l2-enforcer.tmpl	Arista Networks	Switch
7	huawei-switch-l2-enforcer.tmpl Template for SNMP policy enforcement with Huawei switches	huawei-switch-l2-enforcer.tmpl	Huawei	Switch
8	alcatel-switch-l2-enforcer.tmpl Template for SNMP policy enforcement with Alcatel-Lucent switches	alcatel-switch-l2-enforcer.tmpl	Alcatel-Lucent	Switch

2. Admin can also choose to create a new template. Click **New Template**.

[Network Access > Network Infrastructure Device > Templates > New Template](#)

New Template

* Name: Label to reference this template.

Description:

* Template File: [Browse](#) No file chosen Template file

[Save Changes](#)

* indicates required field

3. Enter the template name.
4. Enter the description.
5. Click **Browse** and upload the created template file.
6. Click **Save Changes**.

(Optional) Creating an ACL

The Admin can configure ACL in 2 ways:

- Logging into the Switch console and creating the ACLs manually. Ensure that the configured ACL name is same while creating the SNMP client and policy in IPS.
- Creating the ACLs on IPS, which will push the ACLs to the switches belonging to the corresponding Location Group.

Creating an ACL in IPS is not applicable if Enforcement attribute is VLAN.

To create an ACL on IPS:

1. Select **Endpoint Policy > Network Access > ACL**.
2. Click **New ACL**.
3. Enter the Name
4. Enter the ACL number.
5. Set the Location Group.

6. Under ACL Rules:

- Specify the Protocol.
- Enter the Destination IP address
- Enter the Destination Port
- Specify the action as either permit or deny.
- Click **Add**.

Network Access > Network Infrastructure Device > Access Control List (ACL) > 3COM-Default-ACL

3COM-Default-ACL

*Name: Label to reference this ACL.

Number: Applicable only for H3C. Ensure to use the unused ACL number.

Description:

*Location Group: To manage groups, see the [Location Group](#)

▼ ACL Rules

<input type="checkbox"/>	Protocol	Destination IP / Network	Destination Port	Action	
	<input type="text" value="ip"/>	<input type="text"/>	<input type="text"/>	<input type="text" value="permit"/>	<input type="button" value="Add"/>
<input type="checkbox"/>	ip	192.168.1.0/24		permit	
<input type="checkbox"/>	ip	0.0.0.0/0		deny	

7. Click **Save Changes**.

- Admin can login to the Switch and verify if the ACL is properly configured. ACL name is prefixed with IPS- to distinguish between the ACLs created manually and the one's pushed from IPS.

- ACL name modification is not allowed.

- When deleting an ACL from IPS ensure that it is not applied on any interface or port.

Otherwise, deletion of ACL will not succeed on the Switch.

- ACL configured from IPS should not be modified manually.

- ACL number has to be chosen based on the *Switch configuration guide*. This is required only for the Switches, which create ACLs using ACL number as the key. Ensure that the configured ACL number is not used on the Switch. Currently, ACL number is mandatory only for HP-3com (H3C) switches.

- Alcatel-Lucent Switch (Omni-Switch) doesn't support ACL configuration on the interface. Hence, ACL enforcement is not supported for Alcatel-Lucent Switch (Omni-Switch).

Adding SNMP Client

To add a client using ACL enforcement:

1. Select **Endpoint Policy > Network Access > Network Infrastructure Device**.
2. Click **New**.
3. Enter the name of the client that will be added in the IPS.
4. Enter the description.
5. Enter the IP address of the client.
6. Under Enforcement, select **ACL Enforcement**.

ACL enforcement is supported for all Switches supporting SSH.

7. Select the Location Group.
8. Select default ACL from the drop down.

Select the Custom option and enter the ACL name if the ACL is configured manually on the Switch.

9. Select the template corresponding to the selected vendor.
10. Under SSH settings:
 - Specify the Authentication Method.
 - Enter the user name, password and port number if authentication method is Password OR
 - Enter the user name, key and pass-phrase if the authentication method is Public Key.
11. Under SNMP settings, specify the SNMP version.
12. Specify the Read username, Read Security Level, Auth Protocol, and Auth Password.
13. Click **Save Changes**.

Configuration Commands for Cisco

The following is a sample configuration for linkup/linkdown/MAC notification traps for SNMP v2c. In the below configuration snmp server is configured as IPS, which is receiving SNMP traps.

You must execute the following commands in configuration mode.

Execute the following command to globally enable linkup and linkdown traps.

```
snmp-server enable traps snmp linkdown linkup
```

```
snmp-server enable traps mac-notification
```

Execute the following command to configure IPS as an snmp-server host, which receives SNMP notifications.

```
snmp-server host <IPS IP Address> trap version 2c public snmp mac-notification
```

```
mac-address-table notification interval 0
```

```
mac-address-table notification
```

```
mac-address-table aging-time 3600
```

```
snmp-server community string ro
```

```
snmp-server community string rw
```

Cisco SNMP v3 configuration

The following commands show a sample configuration for configuring SNMP v3 on Cisco switch. In the below configuration snmp server is configured as IPS, which is receiving SNMP traps.

You must execute the following commands in configuration mode.

```
snmp-server view <Read-View Name> iso included
```

```
snmp-server view <Write-View Name> iso included
```

The below configuration applies when the SNMP v3 settings for Security Level is "Auth, Prev" on IPS.

```
snmp-server group <snmpv3 group name> v3 priv context vlan- match
```

```
snmp-server group <snmpv3 group name> v3 priv read <Read-View Name>
```

```
write <Write-View Name>
```

```
snmp-server user <snmpv3 username> <snmpv3 group name> v3 auth
sha/md5 <auth password> priv aes/des <128> <password>
snmp-server enable traps snmp authentication linkdown linkup
coldstart warmstart
snmp-server host <IPS IP Address> version 3 auth/priv <snmpv3
username> snmp
```

The below configuration applies when the SNMP v3 settings for Security Level is "Auth, NoPrev" on IPS.

```
snmp-server group <snmpv3 group name> v3 auth read <Read-View Name>
write <Write-View Name>
snmp-server group <snmpv3 group name> v3 auth context vlan- match
prefix
snmp-server user <snmpv3 username> <snmpv3 group name> v3 auth
sha/md5 <auth password>
snmp-server host <IPS IP Address> version 3 auth <snmpv3 username>
```

The following sample shows the command, which are executed at interface level.

```
switchport mode access
switchport access vlan 4
snmp trap mac-notification added
```

Configuring Port Security Traps

The following sample shows the commands that is executed at global set up level for configuring port security traps.

```
snmp-server enable traps port-security
snmp-server enable traps port-security trap-rate 1
snmp-server host 192.168.1.5 version 2c public port-security
The following sample shows the commands, which are executed at
interface level.
switchport access vlan <default vlan>
switchport port-security
switchport port-security maximum 2
switchport port-security maximum 1 vlan access
switchport port-security violation restrict
switchport port-security mac-address <dummy mac address>
```

Configuring Cisco ACL

The following sample shows the command for default ACL.

```
#show ip access-lists snmp-default-acl
Extended IP access list snmp-default-acl
  10 deny ip any any
#show run int gi 1/0/7
interface GigabitEthernet1/0/7
The default ACL is pushed from IPS
  ip access-group <Default-ACL>
end
```

The following sample shows the command for Restrict ACL.

```
#show ip access-lists snmp-restrict-acl
Extended IP access list snmp-restrict-acl
  10 permit tcp any host <IPS-IP Address>
  20 permit tcp any host <IPS-IP Address> eq 443
  30 permit tcp any host <IPS-IP Address> eq www
  100 deny ip any any
#show run int gi 1/0/7
interface GigabitEthernet1/0/7
The Restrict ACL name is pushed from IPS.
  ip access-group <restrict-ACL name>
end
```

The following sample shows the command for Full Access ACL.

```
#show ip access-lists snmp-full-access-acl
Extended IP access list snmp-full-access-acl
  10 permit ip any any
#do sh run int gi 1/0/7
interface GigabitEthernet1/0/7
The Full access ACL is pushed from IPS
  ip access-group <Full-Access-ACL name>
end
```

Configuration Commands for Juniper

rule 1 deny ip destination 0.0.0.0 <wildcard>
```

Policy Enforcement using 802.1X Native Supplicant

Overview

IPS supports 801.X authentication using native supplicants. The Native supplicant is the default Operating System (OS) agent, which runs on the client machine. The mobile platforms and laptops have native supplicant support.

The secondary authentication is not supported with 802.1x Native supplicant.

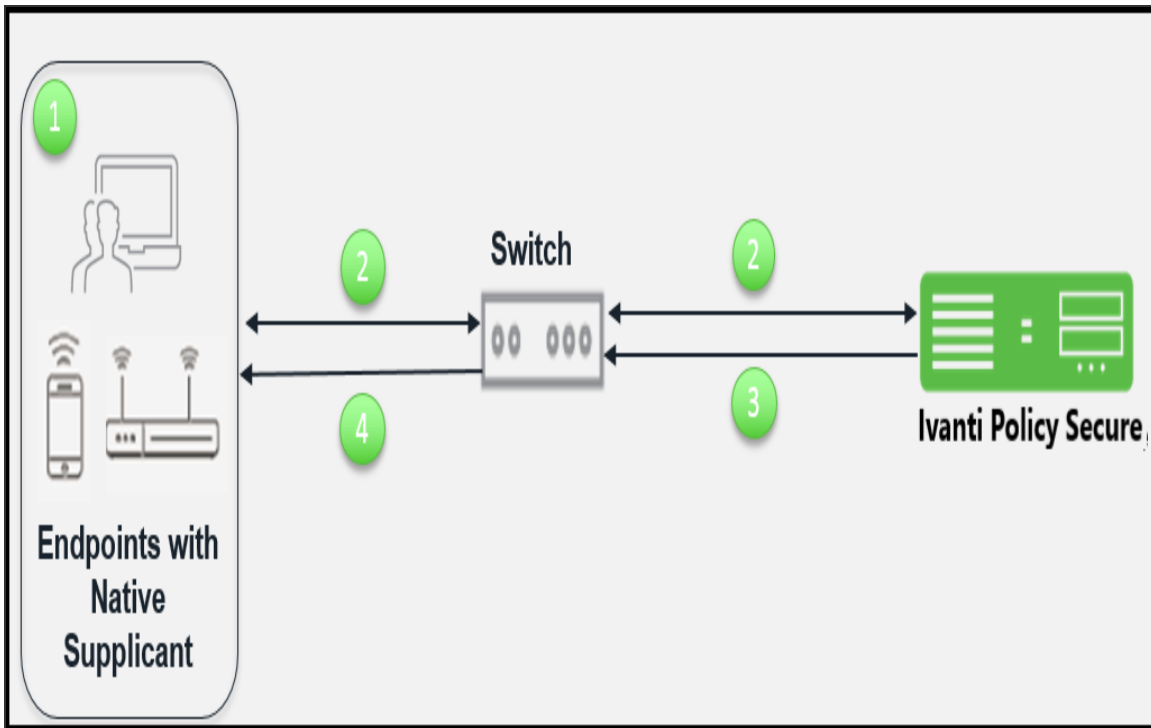

Benefits

- Supports simplified access to applications from personally owned devices, addressing the Bring Your Own Device (BYOD) users.
- Devices that do not have Ivanti Secure Access Client can authenticate with IPS and get the realm and roles applied.

Deployments using 802.1X Authentication with Native Supplicant

802.1X Authentication with Native Supplicant

Using IPS, you can provision 802.1X authentication for endpoints using native supplicant. The Layer 2 authentication and enforcement is used to control network access policies at the edge of the network using an 802.1X enabled switch or access point.

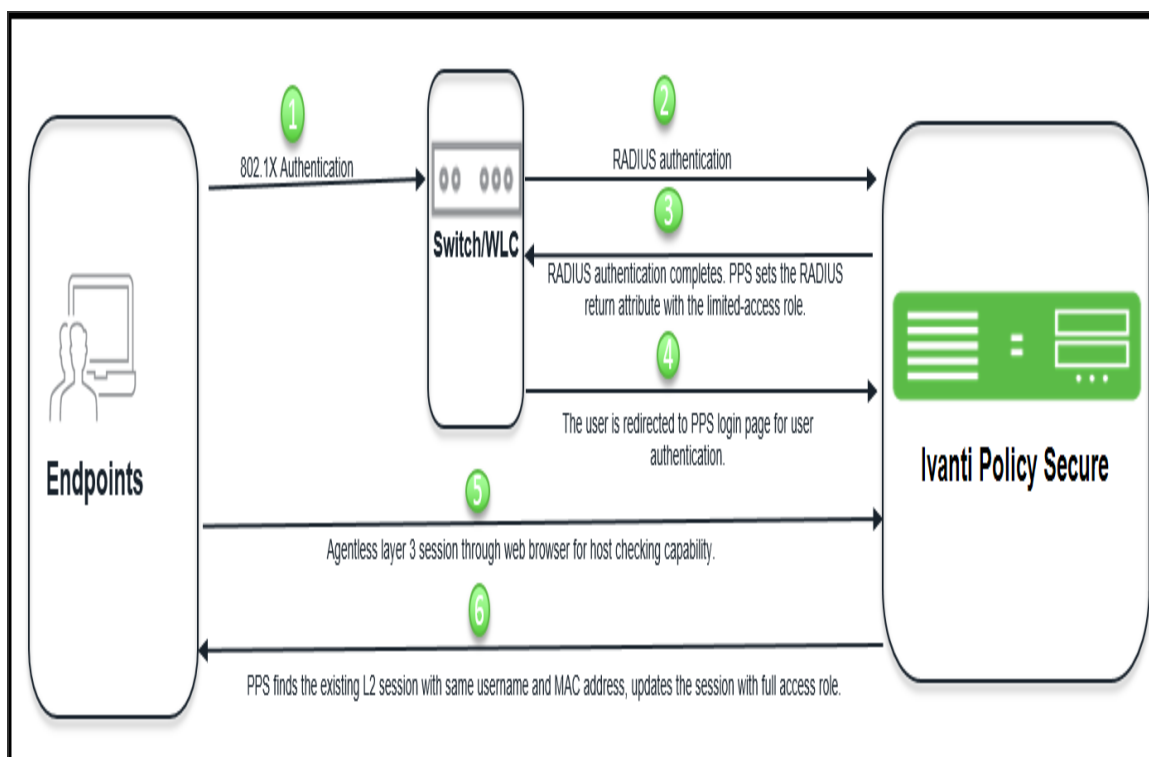

The workflow for 802.1X authentication with native supplicant is described below:

1. Configure the endpoints protocols from the Adapter settings as per the IPS configured protocols. Once the client adapter is online the authentication starts automatically.
2. Switch receives the request and starts RADIUS authentication with IPS. The user is prompted for user credentials.
3. IPS assigns the roles based on the credentials provided by the user. IPS communicates the enforcement rules to switch in form of RADIUS return attributes (For example, Change of VLAN) for the authenticated user.
4. Switch provides access and IP address to the endpoints based on the RADIUS return attributes.

Agentless Host Checking with Native Supplicant

As many users bring their own devices, additional intelligence must be applied to eliminate intrusions and protect sensitive information. The IT administrators need the ability to control where devices are allowed on the network, based on the device type, operating system, owner of the device and user log in credentials of the device. The network resource request must be handled appropriately and appropriate action must be taken for any violation, which includes limiting access to internet only.

The IPS solution provides endpoint compliance for BYOD devices for providing seamless access to protected resources with native supplicant. For example, enterprise users need to provide onsite access to employees and contractors. To provide network access, the BYOD devices from contractor must be compliant to host checker security policies. For such users, you can use 802.1X authentication using native supplicant and then endpoint compliance check is achieved using a web browser. A single session is created for both the connections and a single license is consumed.

The workflow is described below:

1. The contractor user connects to network, performs layer 2 authentication using AD credentials. For 802.1X, AD username and password is used for authentication. For MAC authentication, endpoints MAC address or device attributes for profiler is used for authentication.
2. The endpoint host check is not performed and hence the user gets limited connectivity. The user must be compliant to host check security policy for full access.
3. IPS sets the RADIUS return attribute with limited access role. Limited access role is applied on the endpoint.
4. The user is redirected to a IPS log in page for user authentication.

5. The user opens the web browser and enters the AD username and password. The agentless Host Checker provides the compliance details to IPS.
6. IPS finds the existing session with the same username and MAC address and then updates the session with full access role.

The user gets the required full access to protected resources if the system is compliant to HC security policies.

- The user can choose to remember the username and password to avoid entering it multiple times for layer 2 and layer 3 connections.
 - This feature is supported for Windows and MAC OSX.
 - For configuration, see [Configuring Agentless Host Checking with Native Supplicant](#).
-

Host Checking with Native Supplicant

On Mac OSX, Windows, and Linux endpoint using native supplicant, IPS Host checking can be enforced only for Layer 3 connection. Once the endpoint gets authenticated using native supplicant and gains network access, you can launch and install Ivanti Secure Access Client using web browser deployment or SCCM advertisement to establish a Layer 3 session. This evaluates the health status of the endpoints and thereby ensuring legitimate resource access behind IPS Enforcer.

There will be only one session for Layer 2 and Layer 3 connections on IPS which will consume single license.

For agentless host checking, native supplicant is used to perform 802.1x authentication. The compliance check is performed using browser based agentless L3 session. The L2 and agentless L3 session are bridged on IPS to provide compliance based layer 2 access control. For access control, RADIUS return attribute Filter-ID with Radius COA is used.

The Host Checker functionality is not supported on the native Mozilla browser on MAC OSX. As a workaround disable the Captive Network Assistant feature, which is enabled by default or open the Ivanti Secure Access Client using a different web browser.

Using Native Supplicant the Host Checker functionality is not supported. This is possible through [Configuring Agentless Host Checking with Native Supplicant](#).

Agentless Session Bridging requires Host Checker functionality to be executed on Linux via JAVA NPAPI plugin, which is only supported on Firefox ESR browser with v52.0 and lower.

Configuring Agentless Host Checking with Native Supplicant

The access control for this use case can be achieved through RADIUS CoA and a sample workflow is described below:

1. The native supplicant performs 802.1X authentication and IPS creates a session. The IPS assigns a limited access role since the host check is not performed.

- The user configures the RADIUS URL-redirection attributes on the Cisco Switch. Using RADIUS URL-Redirection return attributes the Cisco switch redirects any initial HTTP/s traffic to IPS so that Layer 3 authentication is performed along with compliance check. Upon successful Host Check, a different set of radius attributes is pushed using Radius CoA to seamlessly access any resource.

You must configure the following return attributes (supported only on Cisco switches):

```
Cisco-AVPAIR=url-redirect-acl=REDIRECT_To_IPS
```

```
Cisco-AVPAIR=url-redirect=https://<IPS-SIGN-IN-URL>/
```

The following figure shows a sample IPS configuration for URL-redirection on Cisco switch.

The screenshot displays the 'RADIUS Attributes' configuration page. It includes options for 'Open port', 'VLAN' (1-4094), and 'Return Attribute'. A table lists configured attributes, with one entry highlighted in yellow and a red box around it:

Return Attribute	Radius Auth Server Attribute Value	Auth Server Catalog Attribute Value	Value
Filter-Id	-none-	-none-	
Cisco-AVPAIR	-none-	-none-	url-redirect=https://10.204.8

Below the table, there are checkboxes for 'Add Session-Timeout attribute with value equal to the session lifetime' and 'Add Termination-Action attribute with value equal 1'. The 'Interface' section is collapsed. The 'Roles' section shows three radio buttons for policy application: 'ALL roles' (selected), 'SELECTED roles', and 'OTHER THAN those selected below'. Below these are lists of 'Available roles' (Guest, Guest Admin, Users, r1, r2) and 'Selected roles' (none), with 'Add ->' and 'Remove' buttons. A note at the bottom states: 'NOTE: changes to this page will cause all L2 clients to drop their connections and reconnect.' At the bottom are 'Save Changes' and 'Save as Copy' buttons.

- The user configures the RADIUS CoA attributes. The recommended radius return attribute to perform access control using RADIUS CoA is Filter-ID for wired devices and ACL-name for WLC.

You must configure the following return attributes on IPS:

```
Filter-Id=PERMIT-ALL.in
```

```
CiscoAVPAIR=subscriber:command=reauthenticate
```

```
Cisco-AVPAIR=subscriber:reauthenticate-type=last
```

The following figure shows a sample IPS configuration for RADIUS CoA.

Network Access > RADIUS Return Attributes Policies

RADIUS Return Attributes Policies

RADIUS Dictionary | RADIUS Vendor | Location Group | RADIUS Client | **RADIUS Attributes** | SNMP Device | SNMP Enforcement Policies

Return Attributes | Request Attributes | Attribute Logging

Show policies that apply to: All roles [Update](#)

A RADIUS return attributes policy specifies the return list attributes to send to an 802.1X network access device, such as which VLAN endpoints must use to access the network. If no policy applies, Open Port is the default action.

[New Policy...](#) [Duplicate](#) [Delete...](#) [↑](#) [↓](#) [Save Changes](#)

		Policies	Attributes	Location Group	Interface	Applies to role
<input type="checkbox"/>	1.	contractor-policy-wireless	ACL-Name=PERMIT-ALL Cisco-AVPAIR=subscriber:command=reauthenticate Cisco-AVPAIR=subscriber:reauthenticate-type=last	WIRELESS-LG	N/A	contractor
<input type="checkbox"/>	2.	contractor-policy-wired	Filter-Id=PERMIT-ALL.in Cisco-AVPAIR=subscriber:command=reauthenticate Cisco-AVPAIR=subscriber:reauthenticate-type=last	WIRED_LG	N/A	contractor
<input type="checkbox"/>	3.	remediation-policy	Cisco-AVPAIR=url-redirect-acl=REDIRECT-IQ Cisco-AVPAIR=url-redirect=https://10.204.89.171/test Session-Timeout=43400 Termination-Action=1	WIRED_LG WIRELESS-LG	N/A	remediation

- The agentless L3 authentication is done through web browser and host check is performed. If host check passes the user receives new role (for example, full-access), which provides full access to authorized resources.

- The L2 and L3 connections are merged and the merged session receives full-access role.
- The change of role triggers new RADIUS return attribute policy. The new policy triggers RADIUS CoA and applies new radius attribute, which provides full access to authorized resources.
- VLAN change using CoA is not supported with Cisco Switches. It is recommended to use RADIUS disconnect for VLAN change.
- The RADIUS CoA configuration for various Cisco switch platforms is described below.

Cisco Platform	IOS Version	RADIUS CoA Configuration
3850	16.3	Filter-Id=PERMIT-ALL.in
2960X	15.2	Filter-Id=PERMIT-ALL.in
2960	12.2	Filter-Id=PERMIT-ALL.in Cisco-AVPAIR=subscriber:command=reauthenticate Cisco-AVPAIR=subscriber:reauthenticate-type=last

Configuring 802.1X for Native Supplicant on IPS

This section covers the procedure for configuring 802.1X authentication on IPS.

- Authentication Protocol Set configuration varies among different platforms. For example, MAC OSX supports EAP-TTLS/PAP, EAP-TTLS/MS-CHAP-V2 and PEAP/EAP-MS-CHAP-V2 authentication protocol set when IPS is configured with AD server for user authentication.
- EAP-TTLS/CHAP are supported with local authentication server and not supported on Active Directory.

Configuring Native Supplicant for 802.1X Authentication

Example: Configuring Windows 7 Native Supplicant for IPS 802.1X Authentication

The 802.1X wired LAN Authentication gives you the possibility to connect your device using the cable network (wired). You can use the windows native supplicant for 802.1X authentication.

Requirements

- Your device must be equipped with a LAN interface and meet the standards for connecting to enterprise networks requiring 802.1X authentication.
- Local admin privileges are required on the endpoint.
- The OS security updates are installed and an Antivirus Software is present and up-to-date.
- It is recommended to disable all third-party connection management tools so that the native Windows tool is used.

Configuring the Windows Native Supplicant

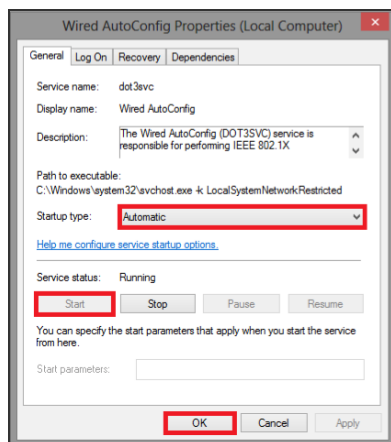

To configure the native supplicant:

1. Select **Control Panel > System and Security > Administrative Tools** and access the Services tool.

In the services window locate the service named **Wired Autoconfig** and double click the service.

WinHTTP Web Proxy Auto-...	WinHTTP i...	Running	Manual	Local Service
Wired AutoConfig	The Wired ...	Running	Automatic	Local Syste...
WLAN AutoConfig	The WLANS...	Running	Automatic	Local Syste...

2. Select the Startup type **Automatic** and click **Start**.

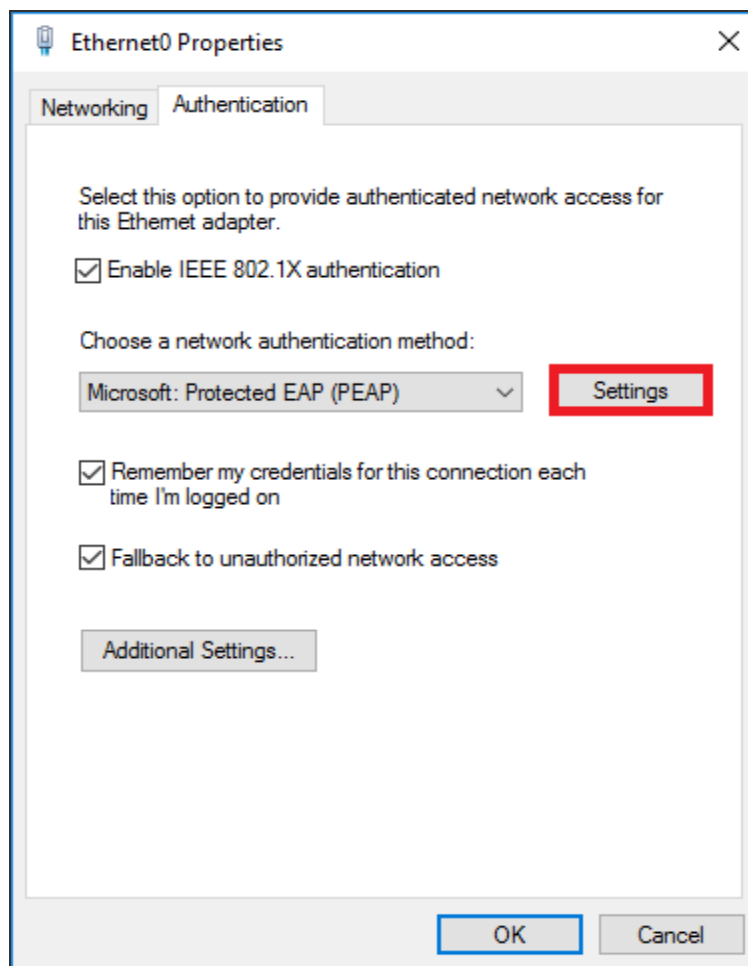

3. Click **Start > Control Panel > Network and Internet > Network and Sharing Center**.

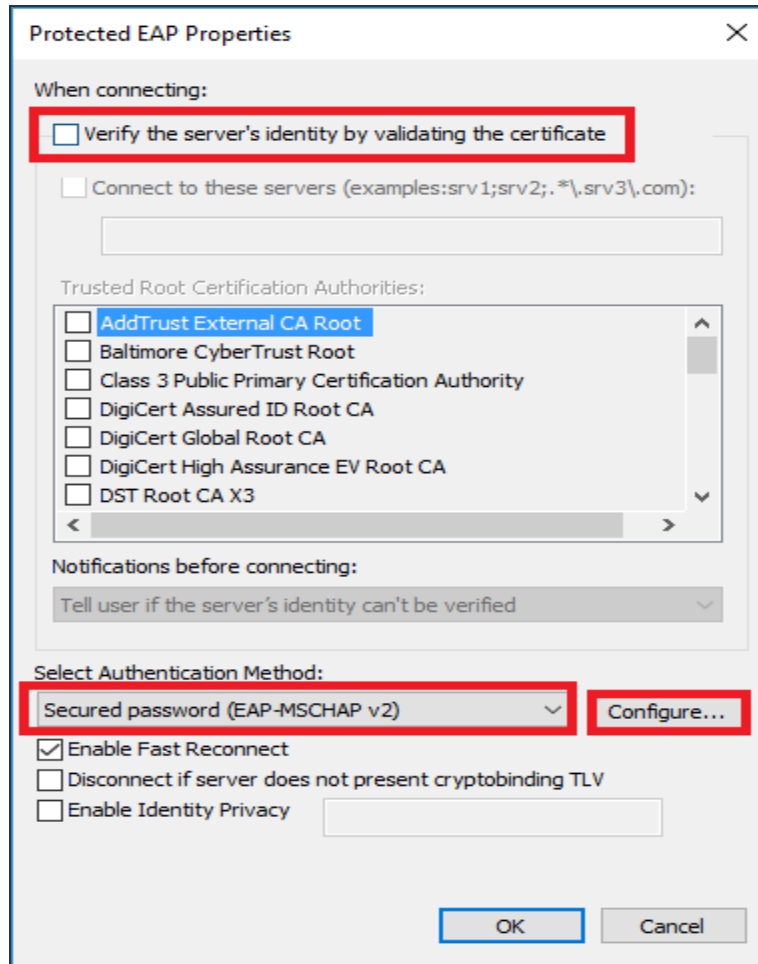

4. Select **Change adapter settings** and then right click on the LAN adapter, Ethernet or Local Area Connection and select Properties.
5. Click the **Authentication** tab at the top of the window. Select **Enable IEEE 802.1X authentication and Fallback to unauthorized network access**. From the dropdown list about the network authentication, choose Microsoft: Protected EAP (PEAP).
6. Click **Settings** to choose the authentication method and then click OK to proceed.

If you choose **Remember my credentials for this connection each time I'm logged on the user credentials** are not prompted for every log in. Don't use this option if multiple people are using the device.

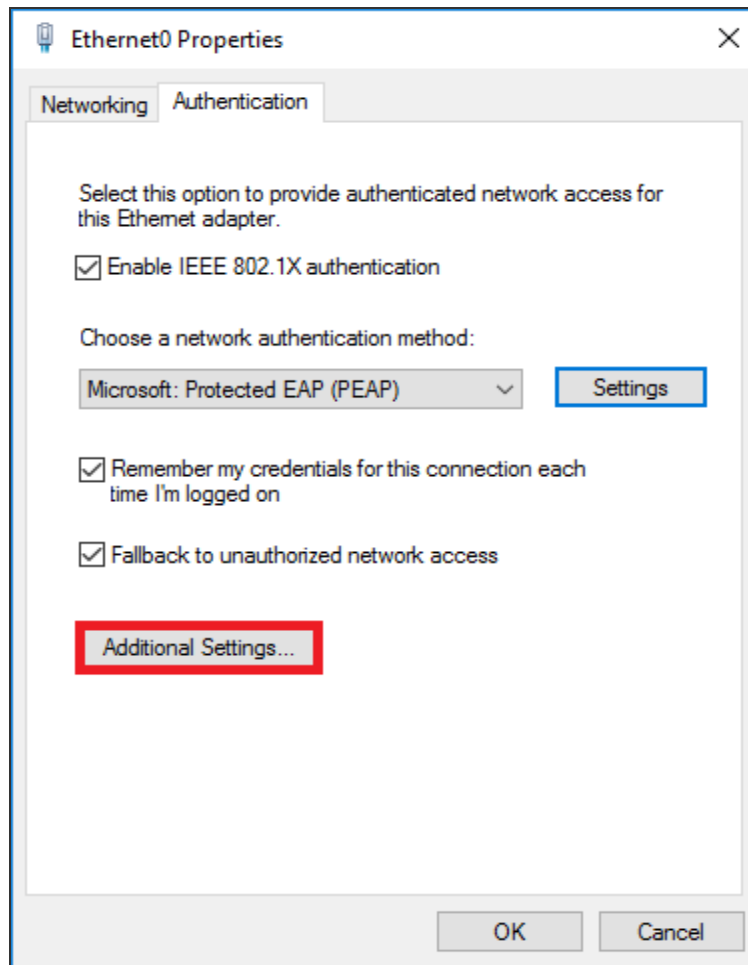

7. Uncheck **Verify the server's identity by validating the certificate** and select the **Enable Fast Reconnect** option. Click **Configure** to continue.

8. Uncheck **Automatically use my Windows logon name and password** and click **OK** to confirm.

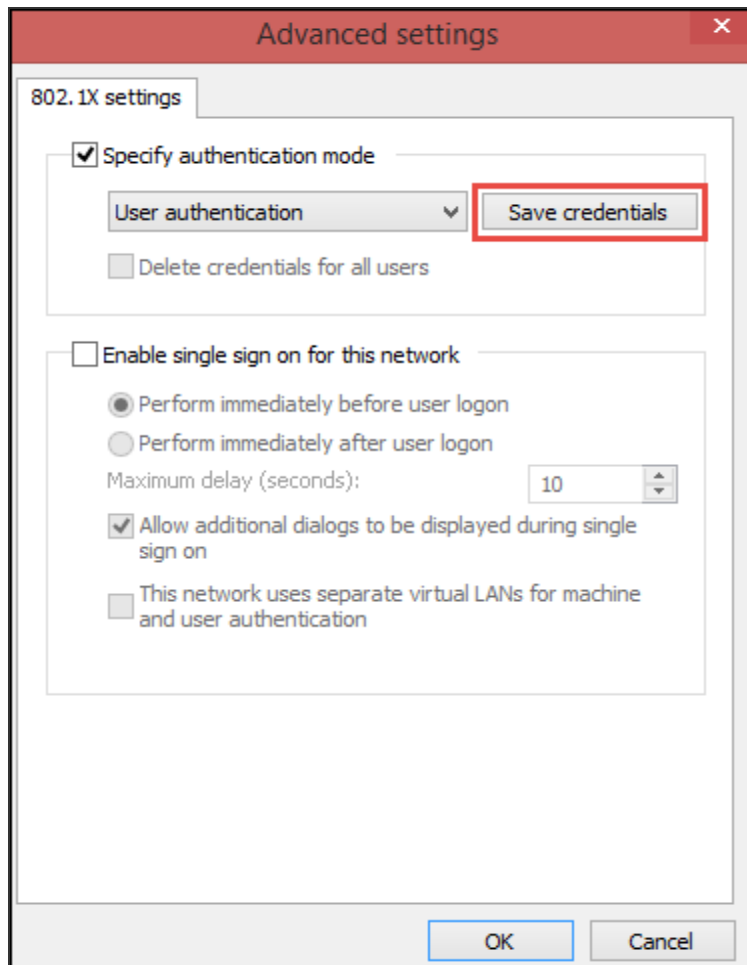

9. Click **Additional Settings**.

10. Select **Specify authentication mode** and choose **User authentication** from the list.

11. If you are using Cisco switch/WLC then you can use Save credentials to save the user credentials.

12. Click **Additional Settings** and choose **User authentication** and then Click **OK**.

13. Plug the network cable and If already inserted, unplug it and attach it again.
14. A log in window pops to enter **Username** and **Password**.

Example: Configuring Mac OSX Native Supplicant for IPS 802.1X Authentication

This section details the procedure for configuring native Mac OSX supplicant for IPS 802.1X authentication.

Requirements:

- Apple Mac OSX endpoint
- iPhone Configuration utility

Configuring MAC OSX Native Supplicant

Authentication to a IPS 802.1X server in MAC OSX endpoints is achieved using Apple Configurator. This tool allows you to easily create, maintain, and install configuration profiles, track and install provisioning profiles, and capture device information including console logs.

The latest MAC OSX endpoints can be configured using Apple Configurator 2 tool.

Configuring 802.1x profile

You can create various profiles (TTLS/PAP, TTLS/MS-CHAP-V2, and PEAP/MS-CHAP-V2) required for IPS 802.1x authentication using Apple Configurator. The generated configuration profiles can be exported to a Mac OSX endpoint. To create profiles, install the profiles (by double clicking on the exported files) on their OSX endpoints and that will provision Layer 2 access when connected to 802.1x enabled switch port.

Configuring 802.1x profiles -TTLS/PAP, TTLS/MS-CHAP-V2, and PEAP/MS-CHAP-V2 applies only for General and Wi-Fi settings. If the authentication server is LDAP, use TTLS-PAP for LDAP servers. If the authentication server is Active Directory or local, use TTLS-MSChapV2 or PEAP-MSChapV2.

Configuring TTLS-PAP Authentication Profile

To configure TTLS-PAP profile, perform the following:

1. On the iPhone configuration utility (IPCU) navigate to **Configuration Profiles** tab.
2. On configuration Profiles page, select General and enter the required values.

The screenshot shows the iPhone Configuration Utility (IPCU) interface for configuring a profile. The left sidebar lists various configuration categories: General (Mandatory), Passcode (Not Configured), Restrictions (Not Configured), Wi-Fi (1 Payload Configured), VPN (Not Configured), Email (Not Configured), Exchange ActiveSync (Not Configured), LDAP (Not Configured), CalDAV (Not Configured), and CardDAV (Not Configured). The main area is titled 'General' and contains the following fields:

- Name:** Display name of the profile (shown on the device). The value 'TTL-PAP' is entered in the text box.
- Identifier:** Unique identifier for the profile (e.g. com.company.profile). The value 'net.pulsesecure.dot1x' is entered in the text box.
- Organization:** Name of the organization for the profile. The value 'Pulse Secure' is entered in the text box.
- Description:** Brief explanation of the contents or purpose of the profile. A text area contains the value 'Profile description.'
- Security:** Controls when the profile can be removed. A dropdown menu is set to 'Always'.

3. Select Wi-Fi and enter the required values.

The screenshot displays the Windows Network and Sharing Center. On the left, a sidebar lists various network settings: General (Mandatory), Passcode (Not Configured), Restrictions (Not Configured), Wi-Fi (1 Payload Configured), VPN (Not Configured), Email (Not Configured), Exchange ActiveSync (Not Configured), LDAP (Not Configured), CalDAV (Not Configured), CardDAV (Not Configured), Subscribed Calendars (Not Configured), Web Clips (Not Configured), and Credentials (Not Configured). The Wi-Fi section is highlighted. The main pane shows the configuration for the selected Wi-Fi network. The Service Set Identifier (SSID) is set to TTLS-PAP. The Auto Join checkbox is unchecked. The Hidden Network checkbox is unchecked. The Proxy Setup is set to None. The Security Type is set to WPA / WPA2 Enterprise. The Enterprise Settings tab is selected, showing the Protocols, Authentication, and Trust sub-tabs. Under Accepted EAP Types, the checkboxes for TLS, LEAP, EAP-FAST, TTLS (checked), PEAP, and EAP-SIM are shown. Under EAP-FAST, the checkboxes for Use PAC, Provision PAC, and Provision PAC Anonymously are shown. Under Inner Authentication, the dropdown menu is set to PAP.

Configuring TTLS/MS-CHAP-V2 Authentication Profile

To configure TTLS/MS-CHAP-V2, perform the following:

1. On the iPhone configuration utility (IPCU) navigate to **Configuration Profiles** tab.
2. On configuration Profiles page, select General and enter the required values.

The screenshot shows the iPhone Configuration Utility (IPCU) interface for configuring a profile. On the left is a sidebar with icons and labels for various settings: General (Mandatory), Passcode (Not Configured), Restrictions (Not Configured), Wi-Fi (1 Payload Configured), VPN (Not Configured), Email (Not Configured), Exchange ActiveSync (Not Configured), LDAP (Not Configured), CalDAV (Not Configured), and CardDAV (Not Configured). The main area is titled 'General' and contains several fields for profile configuration:

- Name:** Display name of the profile (shown on the device). The value 'TTLS-MACHAPV2' is entered in the text box.
- Identifier:** Unique identifier for the profile (e.g. com.company.profile). The value 'net.pulsesecure.dot1x' is entered in the text box.
- Organization:** Name of the organization for the profile. The value '[optional]' is entered in the text box.
- Description:** Brief explanation of the contents or purpose of the profile. The value 'Profile description.' is entered in the text box.
- Security:** Controls when the profile can be removed. A dropdown menu is set to 'Always'.

3. Select **Wi-Fi** and enter the required values.

The screenshot shows the Windows Network Setup window. On the left, a sidebar lists various network-related settings: General (Mandatory), Passcode (Not Configured), Restrictions (Not Configured), Wi-Fi (1 Payload Configured), VPN (Not Configured), Email (Not Configured), Exchange ActiveSync (Not Configured), LDAP (Not Configured), CalDAV (Not Configured), CardDAV (Not Configured), Subscribed Calendars (Not Configured), Web Clips (Not Configured), and Credentials (Not Configured). The Wi-Fi section is selected and highlighted. The main pane displays the Wi-Fi configuration options:

- Service Set Identifier (SSID)**: Identification of the wireless network to connect to. The text box contains "TTLA-MSCHAPV2".
- ☐ **Auto Join**: Automatically join the target network.
- ☐ **Hidden Network**: Enable if target network is not open or broadcasting.
- Proxy Setup**: Configures proxies to be used with this network. The dropdown menu is set to "None".
- Security Type**: Wireless network encryption to use when connecting. The dropdown menu is set to "WPA / WPA2 Enterprise".
- Enterprise Settings**: Configuration of protocols, authentication, and trust. There are three tabs: "Protocols" (selected), "Authentication", and "Trust".
- Accepted EAP Types**: Authentication protocols supported on target network. The options are: ☐ TLS, ☐ LEAP, ☐ EAP-FAST, ☒ TTLS, ☐ PEAP, and ☐ EAP-SIM.
- EAP-FAST**: Configuration of Protected Access Credential (PAC). The options are: ☐ Use PAC, ☐ Provision PAC, and ☐ Provision PAC Anonymously.
- Inner Authentication**: Authentication protocol (for use only with TTLS). The dropdown menu is set to "MSCHAPv2".

Configuring PEAP Authentication Profile

To configure PEAP, perform the following:

1. On the iPhone configuration utility (IPCU) navigate to **Configuration Profiles** tab.
2. On configuration Profiles page, select **General** and enter the required values.

The screenshot shows the iPhone Configuration Utility (IPCU) interface. On the left is a sidebar with a list of configuration categories: General (Mandatory), Passcode (Not Configured), Restrictions (Not Configured), Wi-Fi (1 Payload Configured), VPN (Not Configured), Email (Not Configured), Exchange ActiveSync (Not Configured), LDAP (Not Configured), CalDAV (Not Configured), CardDAV (Not Configured), and Subscribed Calendars (Not Configured). The 'General' category is selected and highlighted. The main area is titled 'General' and contains several fields for profile configuration:

- Name:** Display name of the profile (shown on the device). The value 'PEAP' is entered in the text box.
- Identifier:** Unique identifier for the profile (e.g. com.company.profile). The value 'net.pulsesecure.dot1x' is entered in the text box.
- Organization:** Name of the organization for the profile. The value '[optional]' is entered in the text box.
- Description:** Brief explanation of the contents or purpose of the profile. A text area contains the value 'Profile description.'
- Security:** Controls when the profile can be removed. A dropdown menu is set to 'Always'.

3. Select **Wi-Fi** and enter the required values.

The screenshot displays the Windows Network Setup Wizard with the 'Wi-Fi' tab selected in the left-hand navigation pane. The 'Wi-Fi' tab is highlighted and shows '1 Payload Configured'. The main configuration area on the right contains the following sections:

- Service Set Identifier (SSID)**: Identification of the wireless network to connect to. The text 'PEAP' is entered in the input field.
- Auto Join**: ☐ Automatically join the target network.
- Hidden Network**: ☐ Enable if target network is not open or broadcasting.
- Proxy Setup**: Configures proxies to be used with this network. The dropdown menu is set to 'None'.
- Security Type**: Wireless network encryption to use when connecting. The dropdown menu is set to 'WPA / WPA2 Enterprise'.
- Enterprise Settings**: Configuration of protocols, authentication, and trust. Below this are three tabs: 'Protocols' (selected), 'Authentication', and 'Trust'.
- Accepted EAP Types**: Authentication protocols supported on target network. The options are: ☐ TLS, ☐ LEAP, ☐ EAP-FAST, ☐ TTLS, ☒ PEAP, and ☐ EAP-SIM.
- EAP-FAST**: Configuration of Protected Access Credential (PAC). The options are: ☐ Use PAC, ☐ Provision PAC, and ☐ Provision PAC Anonymously.

Layer 3 Enforcement

Layer 3 enforcement means using devices other than L2 switches or wireless access points for enforcement. This includes adding SRX, ScreenOS, Palo Alto, Fortigate, and Check Point firewall as enforcement points.

Enforcement using Check Point Next-Generation Firewall

Overview

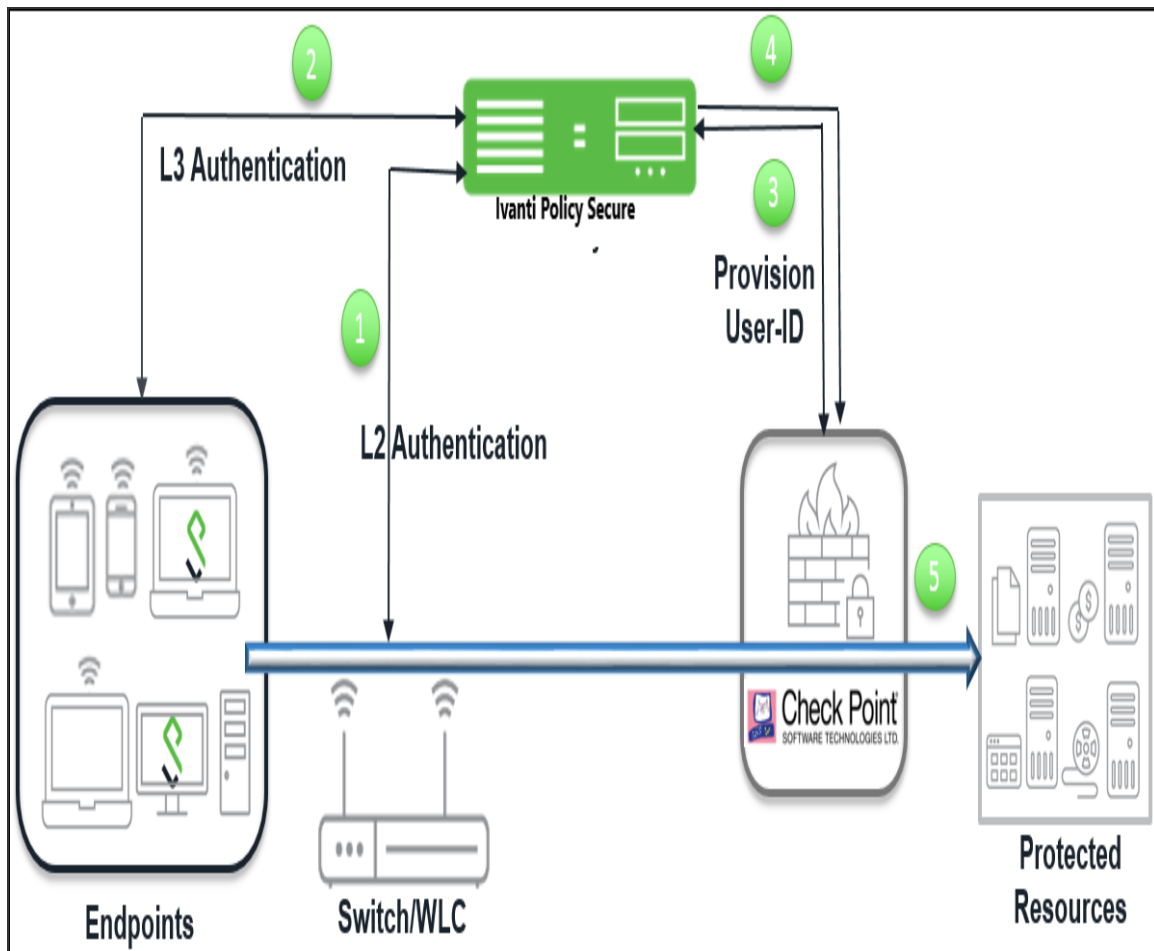

IPS delivers layer 3 network access control solution when deployed with Check Point Next-Generation Firewall (NGFW). IPS authenticates users, ensures that the endpoints meet security policies, and then dynamically updates the firewall enforcement point with the resulting user session information. Upon successful user authentication with IPS, the access to protected resources behind the firewall is based on the user identity, IP address, and user role information provided by IPS.

The IPS and Check Point firewall integration provides identity enabled layer 3 enforcement for BYOD, guests, and enterprise employees and protects corporate sensitive data from unauthenticated access and attacks.

Deployment of IPS using Check Point Next-Generation Firewall

This section describes the integration of IPS with Check Point Next-Generation Firewall. The Check Point Next-Generation Firewall controls the access to resources (for example, internet, CRM systems, Wikis and so on.) based on policy settings that defines the access. The Check Point Next-Generation Firewall allows integration with directory sources (For example, AD or LDAP) to get user and group information. The policies are then defined based on user role information.

IPS serves as the provider of identity information (For example, user-ID, IP address, and roles) for Check Point Next-Generation Firewall. The Check Point Next-Generation Firewall uses the identity information provided by the IPS for deciding the resource access.

The authentication process is described below:

1. The endpoints connect to Switch/WLAN and performs the layer 2 authentication with IPS.
2. IPS performs the layer 3 authentication and performs compliance check on the endpoint and detects for any unauthorized behavior. IPS can also learn endpoint IP address using accounting and provision mapping.
3. IPS provisions the auth table entries (user-ID, IP address, and roles) on the Check Point Next-Generation Firewall.
4. The user role changes, which includes any unauthorized behavior are dynamically updated on the firewall. IPS provisions the auth table with changes in role information if any on Check Point Next-Generation Firewall. The access is based on roles.
5. The Check Point Next-Generation Firewall applies policies to allow or block user access to protected resources.

Configuring IPS with Check Point Next-Generation Firewall

This section covers the configuration of IPS for adding Check Point Next-Generation Firewall as an Infranet Enforcer.

Configuring Check Point Infranet Enforcer in IPS

The IPS configuration requires defining a new Check Point Infranet Enforcer instance on IPS and then fetching the pre-configured shared secret key from the firewall. The shared secret key is used to communicate between the Check Point firewall and IPS. The standard user authentication / authorization configurations such as Auth Table Mapping Policies should also be created and associated with the required roles.

To configure a Check Point Firewall Infranet Enforcer in IPS:

1. Select **Endpoint Policy > Infranet Enforcer**.

The screenshot shows the 'Infranet Enforcer > Infranet Enforcer Connection' page. At the top, there's a breadcrumb 'Infranet Enforcer > Infranet Enforcer Connection' and a title 'Infranet Enforcer Connection'. Below the title is a tabbed interface with tabs for 'Connection', 'Resource', 'IPsec', 'Auth Table Mapping', and 'IP Address Pools'. The 'Connection' tab is active. Below the tabs, a description states: 'A connection policy specifies the connection between the Pulse Policy Secure and Infranet Enforcer.' There are three buttons: 'New Enforcer...', 'Duplicate...', and 'Delete...'. Below these buttons is a dropdown menu set to '10' with the text 'records per page' and a search bar labeled 'Search:'. At the bottom is a table with the following columns: 'Enforcer', 'Serial Numbers', 'Location Group', 'Platform', 'Version', 'FIPS', and 'IP Address'. The table is currently empty.

Enforcer	Serial Numbers	Location Group	Platform	Version	FIPS	IP Address
----------	----------------	----------------	----------	---------	------	------------

2. Click **New Infranet Enforcer** and select **Check Point Firewall** in the **Platform** drop down.

3. Enter the Name and IP Address of the Check Point Next-Generation Firewall and enter the shared secret between IPS and Check Point.

IPS has the default server URL for Check Point R80.10.

Infranet Enforcer > Connection > 10.0.0.100

4. (Optional) Select **Server Certificate Validation** to verify the firewall certificate.
5. Click **Save Changes**.

Configuring Auth Table Mapping Policies

An auth table entry consists of the user's name, a set of roles, and the IP address of the user device. An auth table mapping policy specifies which enforcer device (Firewall) can be used for each user role. These policies prevent the IPS from creating unnecessary auth table entries on all connected enforcer devices.

IPS's default configuration includes only one default auth table mapping policy. When the default auth table mapping policy is enabled, IPS pushes one auth table entry for each authenticated user to the selected Check Point Next-Generation Firewall configured as Infranet Enforcers in IPS.

When you provision the authentication table from IPS to the firewall, ensure that the Profiler is configured with the Profiler Name and upload the FPDB, or do not configure the Profiler. If the Profiler is configured without uploading the FPDB, then the authentication table is not sent from IPS to Firewall.

To configure an Auth Table Mapping Policy:

1. Select **Endpoint Policy > Infranet Enforcer > Auth Table Mapping** and click **New Policy**.

Infranet Enforcer > Infranet Enforcer Auth Table Mapping Policies > New Policy

New Policy

* Name:

Description:

▼ Infranet Enforcer

* Indicates required field

2. On the New Policy page:

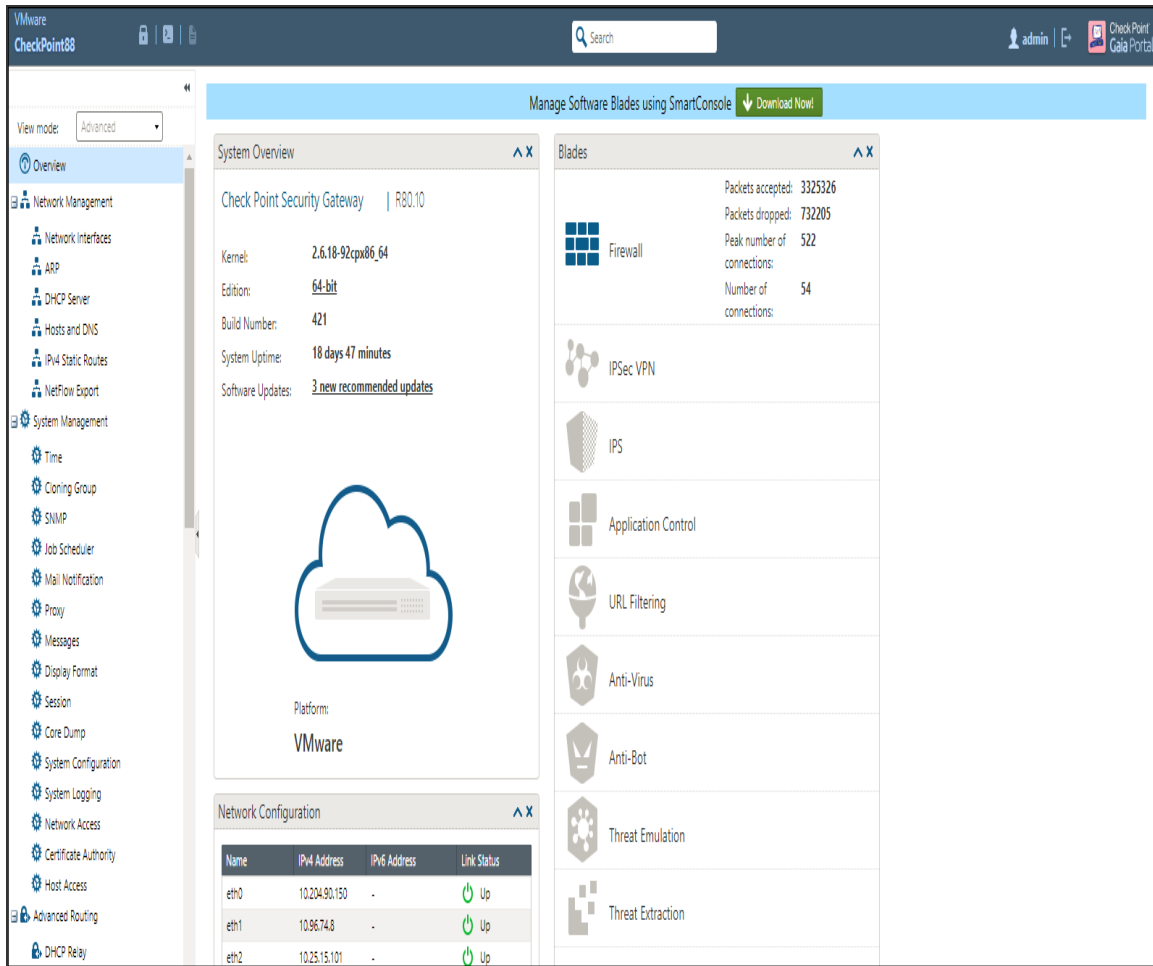

1. For Name, enter a name to label the auth table mapping policy.
2. (Optional) For Description, enter a description.
3. In the Enforcer section, specify the Infranet Enforcer firewall(s) to which you want to apply the auth table mapping policy.
4. In the Roles section, specify:
 - Policy applies to ALL roles-Select this option to apply the auth table mapping policy to all users.
 - Policy applies to SELECTED roles-Select this option to apply the auth table mapping policy only to users who are mapped to roles in the SELECTED roles list. You can add roles to this list from the available roles list.
 - Policy applies to all roles OTHER THAN those selected below-Select this option to apply the auth table mapping policy to all users except for those who map to the roles in the SELECTED roles list. You can add roles to this list from the available roles list.
5. In the Action section, specify auth table mapping rules for the specified Infranet Enforcer.
 - Always Provision Auth Table-Select this option to automatically provision auth table entries for chosen roles on the specified Infranet Enforcer.
 - Provision Auth Table as Needed-Select this option to provision auth table entries only when a user with a chosen role attempts to access a resource behind the specified Infranet Enforcer. This option is greyed out for Check Point Firewall Enforcers since it is not supported.
 - Never Provision Auth Table-Select this option to prevent chosen roles from accessing resources behind the specified Infranet Enforcer.
6. You must delete the Default Policy if you configure any custom auth table mapping policies. IPS's default configuration includes this default auth table mapping policy that allows all source IP endpoints to use all Infranet Enforcers.

7. Click **Save Changes**.

Configuring Check Point Next-Generation Firewall

Check Point firewall detects traffic from an endpoint that matches a configured security policy using the access roles. It determines the role(s) associated with that user, and allows or denies the traffic based on the actions configured in the security policy.

The network interfaces are configured on the Check Point Next-Generation firewall and the remaining configurations are done on the Check Point Smart Console.

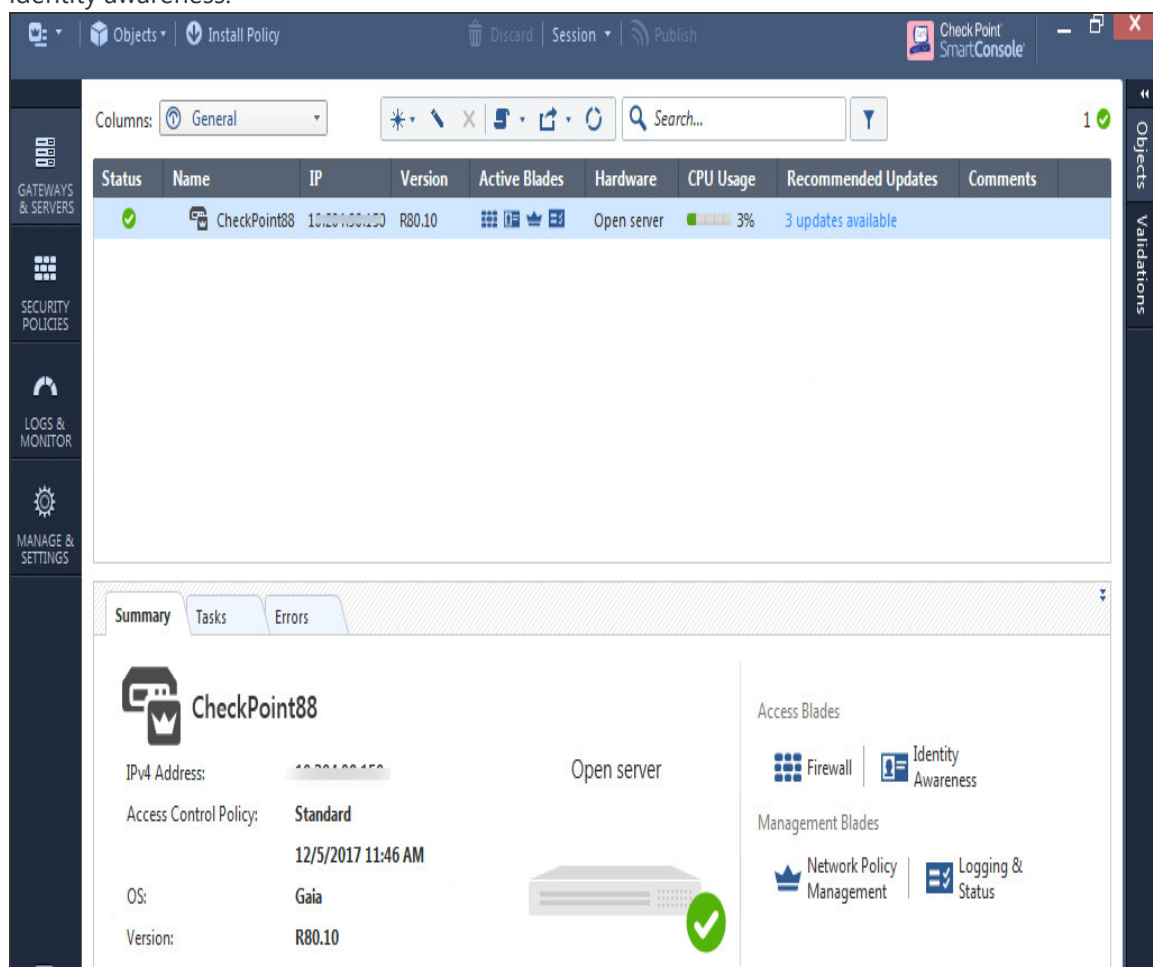

Configuring Identity Awareness in SmartConsole

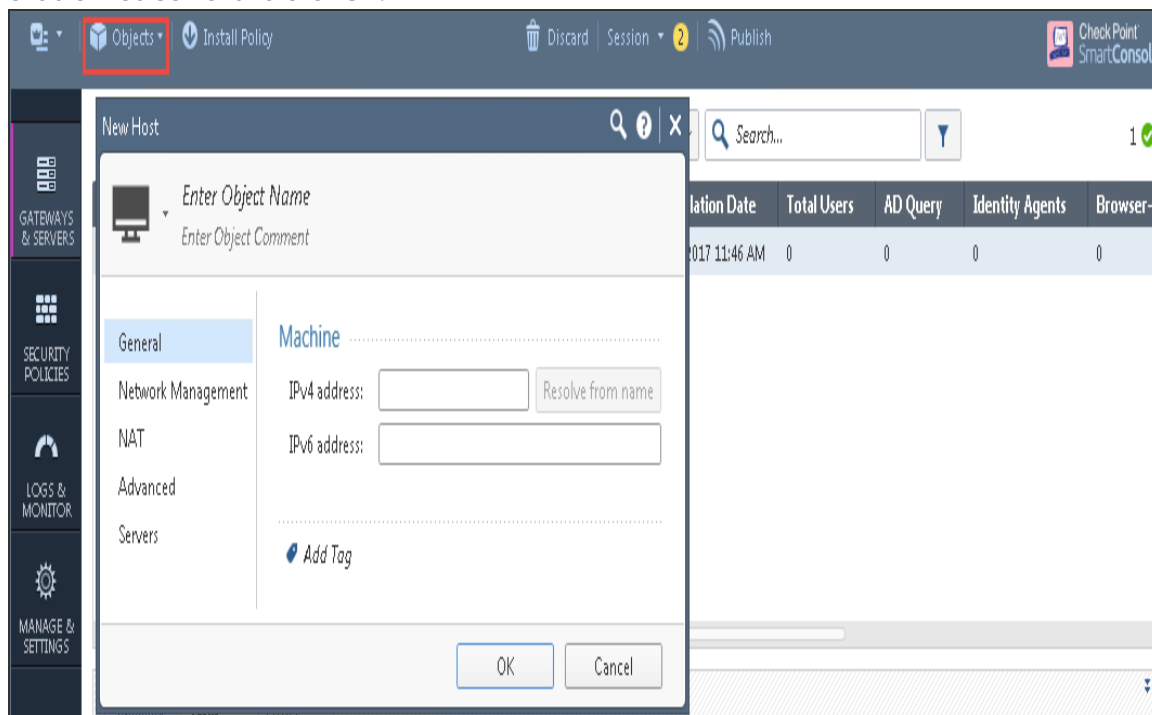

The Identity Awareness lets you easily configure network access and auditing based on network location, identity of user, and identity of the device. When Identity Awareness identifies a source or destination, it shows the IP address of the user or computer with a name. For example, this lets you create firewall rules with any of these properties. You can define a firewall rule for specific users when they send traffic from specific computers or a firewall rule for a specific user regardless of which computer they send traffic from.

To enable Identity awareness:

1. Login to the Check Point SmartConsole.
2. From the **Security & Gateways view**, double-click the Security Gateway on which to enable identity awareness.

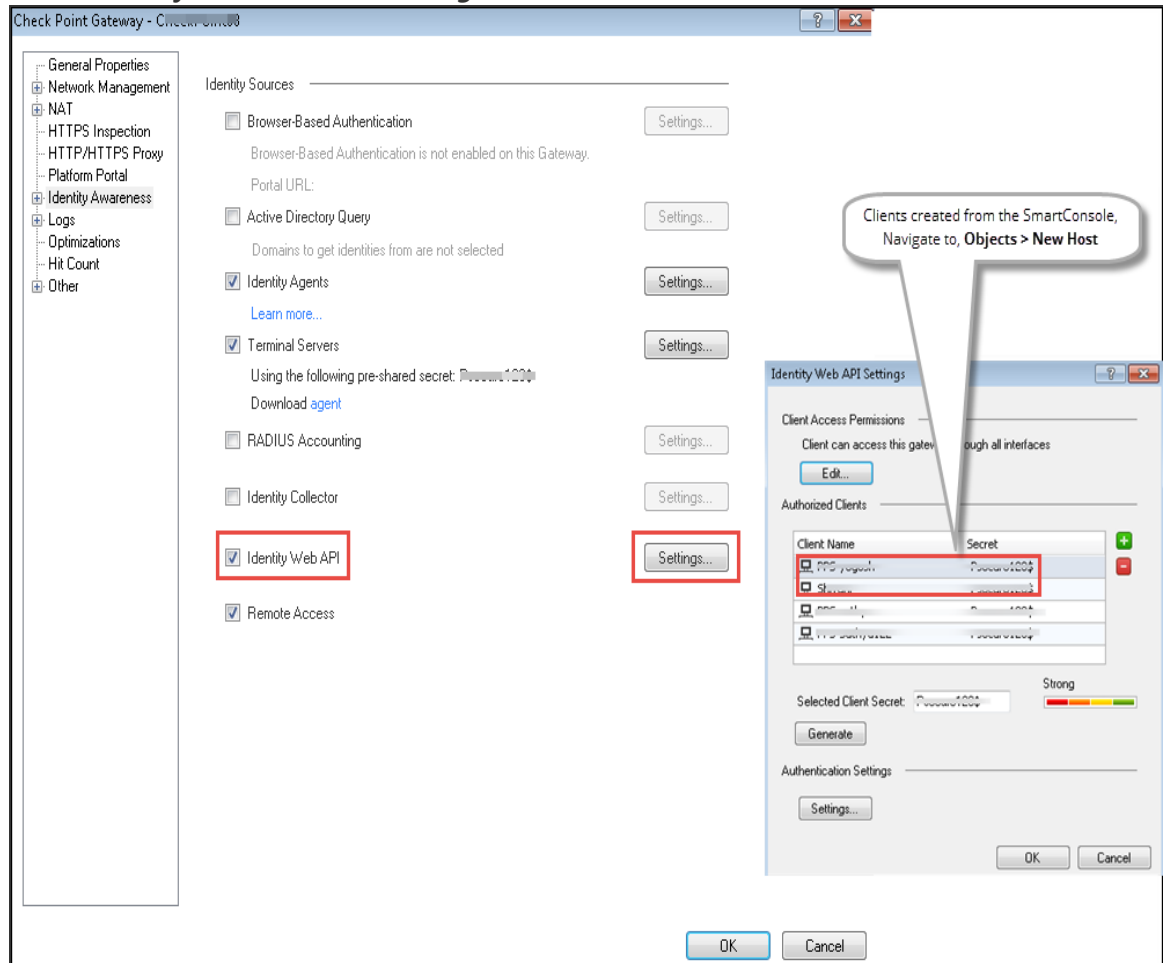

3. Create an object for IPS. Select **Objects > New Host** and enter the IPS IP address. Under Servers, enable Web Server and click **OK**.

4. Select **Gateways & Servers > Identity Awareness** and enable the following options:

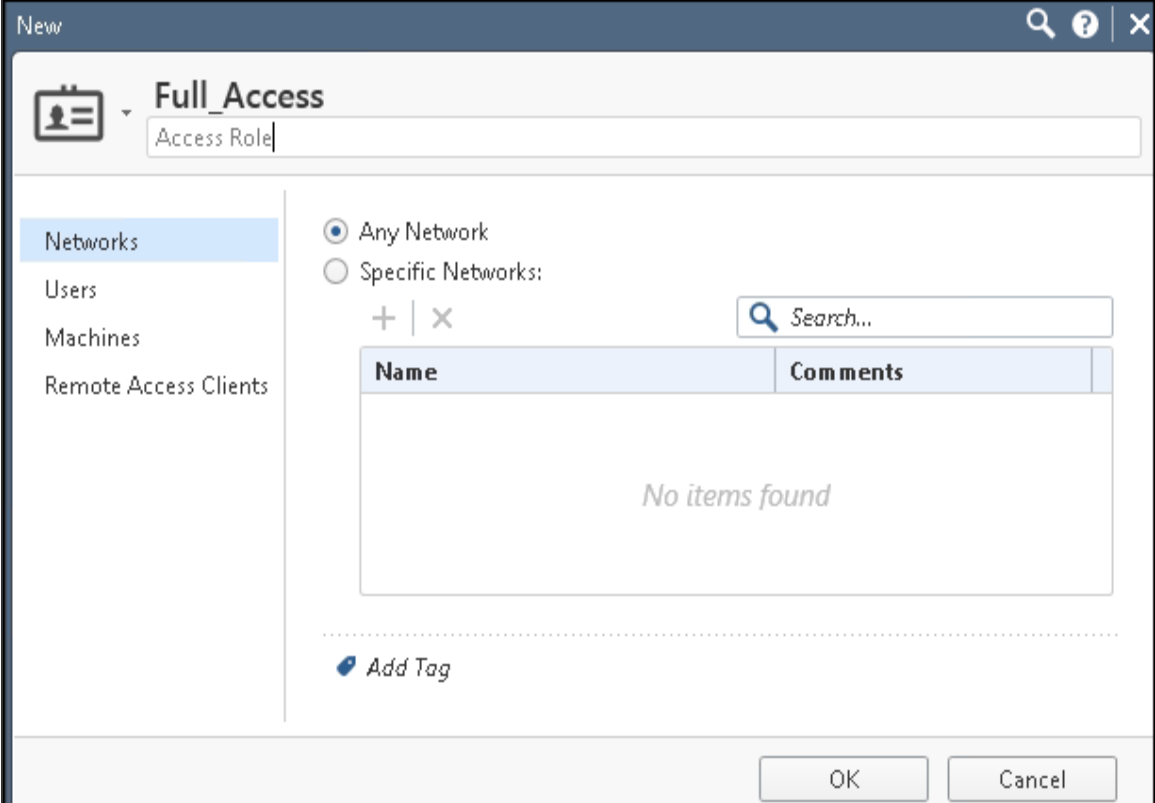

- **Terminal Servers**- Note down the pre-shared secret key.
- **Identity Web API**- Click **Settings** and add the IPS device as Authorised Clients.

5. Click **Install Policy**.

- From the Object Explorer create an object for Identity matching by creating user roles. Select Objects > Object Explorer and Click **New > Users > Access Role**.

 The role names must match with the Role names created on IPS.

New

 **Full_Access**

Access Role

Networks
Users
Machines
Remote Access Clients

☒ Any Network

 Search...

Name	Comments
No items found	

 Add Tag

OK Cancel

7. From the SmartConsole, create a security policy by keeping the Access Role in Source column. Select **Security Policies > Access Control > Policy** and then configure the required policies. For example, Full_Access policy allows traffic from Client with Full_Access role, Limited_Access role policy denies traffic from Client with Limited_Access role, and default_allow policy which allows all traffic. The Full_Access role is on the top of the list since it should be considered first.

8. Click **Install Policy**.

Troubleshooting

You can use the following CLI commands (Expert Mode) on the Check Point firewall for troubleshooting:

- *pdp monitor all* - Displays the table of user identities mapped to IP addresses.

Unsupported Features

The following features are not supported:

- IP Address Pools
- IPsec Enforcement
- IDP Sensors
- Virtual Systems (VSYS)

- Enforcement for endpoints behind Network Address Translation (NAT)
- Resource access policies. The administrator should configure all firewall policies on the firewall through smartboard

Enforcement using Palo Alto Networks Firewall

Overview

IPS delivers layer 3 network access control solution when deployed with Palo Alto Networks next-generation firewalls. IPS authenticates users, ensures that the endpoints meet security policies, and then dynamically updates the firewall enforcement point with the resulting user session information. Upon successful user authentication with IPS, the access to protected resources behind the firewall is based on the user identity, IP address, and user role information provided by IPS.

The IPS and PAN integration provides identity enabled layer 3 enforcement for BYOD and guests as well as enterprise employees, with the end authentication and comprehensive compliance checks from IPS.

Deployment of IPS using PAN Firewall

This section describes the integration of IPS with Palo Alto Networks next-generation firewall. The IPS and PAN firewall integration allows users to enforce role based access to network resources and web applications and ensures endpoint compliance. The integrated solution provides policy enforcement for end to end protection of sensitive corporate data from unauthenticated access and attacks.

IPS combines user identity and device security state information with network location to create a unique, session specific access control policy for each user. The Palo Alto Networks firewall provides a feature called User Identification (User-ID) that creates policies and performs reporting based on users and groups rather than individual IP addresses. IPS uses the User-ID XML API to send the IP address to user and IP address to Group (Role) mapping information to the Palo Alto Networks firewall. PAN firewall enables the flexibility to apply different rules to the same server based on tags. A tag is a metadata element, which defines its role on the network, the operating system, or the different kinds of traffic it processes.

The Palo Alto Networks firewall compares the user information against the tag that is associated to a security rule. If the User Role name matches the tag, then traffic is either allowed or denied based on the configuration. When a user logs in, Ivanti Policy Secure provisions their user ID, IP address of the endpoint, and role information to the Palo Alto Networks firewall; that enables firewall policies based on any of these attributes to be enforced.

Similarly, when a user logs out, the user ID, IP address of the endpoint, and role information is removed from the firewall. More importantly, when a user's role changes, the role change information is dynamically updated on the firewall, so that access based on the updated roles is automatically changed based on the policy matched by the new information.

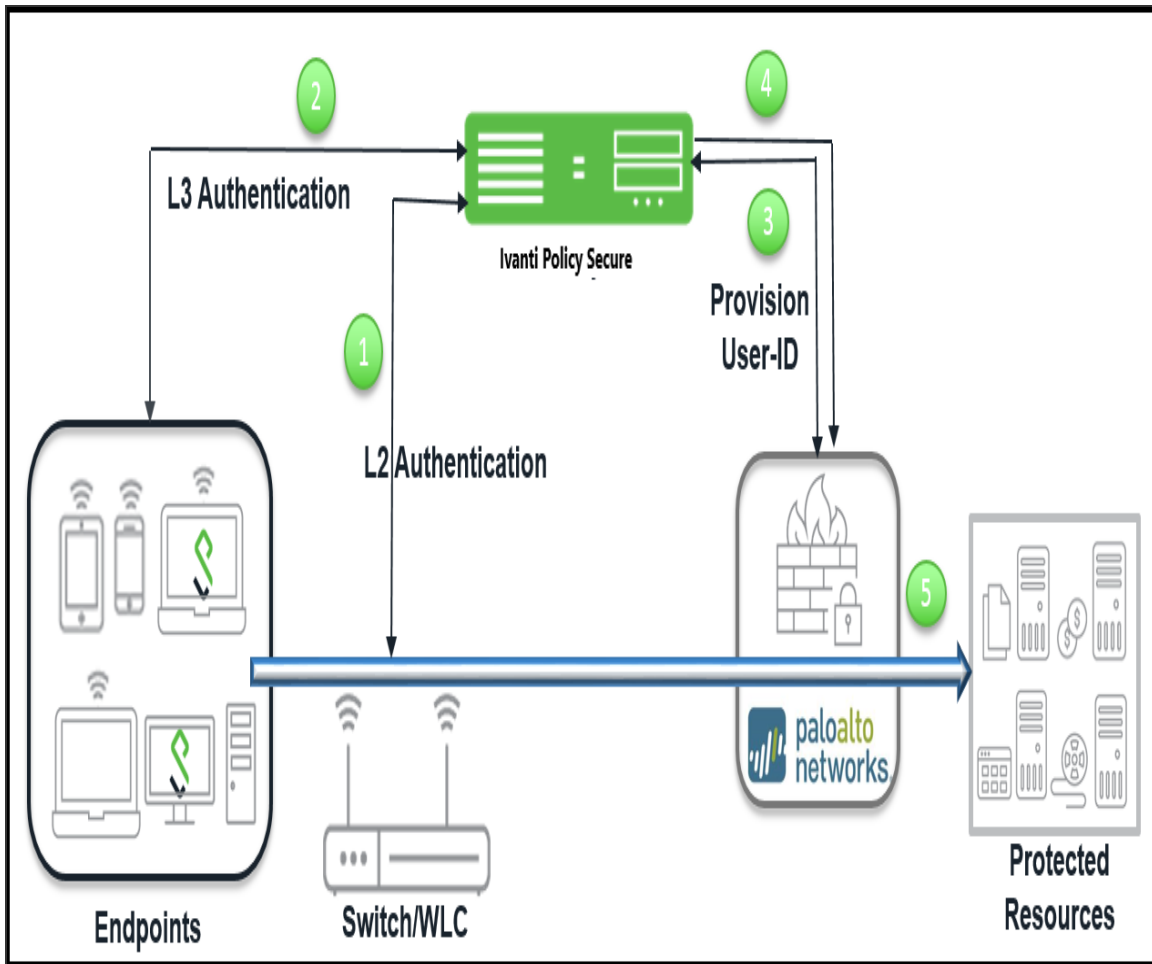

With Palo Alto Networks firewall integration, all users' role changes, which includes compliance check failure or unauthorized behavior are dynamically updated on the firewall. The access is based on user roles and not merely on source IP addresses.

IPS is the policy decision point that determines which users and endpoints can access protected resources. Palo Alto Networks Next Gen firewalls serve as the policy enforcement points to provide the ultimate protection to ensure that network assets are secured.

Palo Alto Networks integration with Ivanti Policy Secure leverages dynamic role information provisioned to the firewall upon user session establishment and for the duration of the session. Ivanti Policy Secure also communicates user information to the Palo Alto Networks firewall when users log in or log out from their device.

Deploying IPS with a PAN firewall for a Small Enterprise

IPS and PAN integration can be used for role based layer 3 access control. For small scale enterprise deployment, you can use a single IPS and PAN firewall as it involves less number of users. For example, employees, contractors, and guest users. A single IPS device provisioning to a PAN firewall can handle up to 30,000 user sessions. The following is a sample deployment with a IPS device along with a PAN firewall.

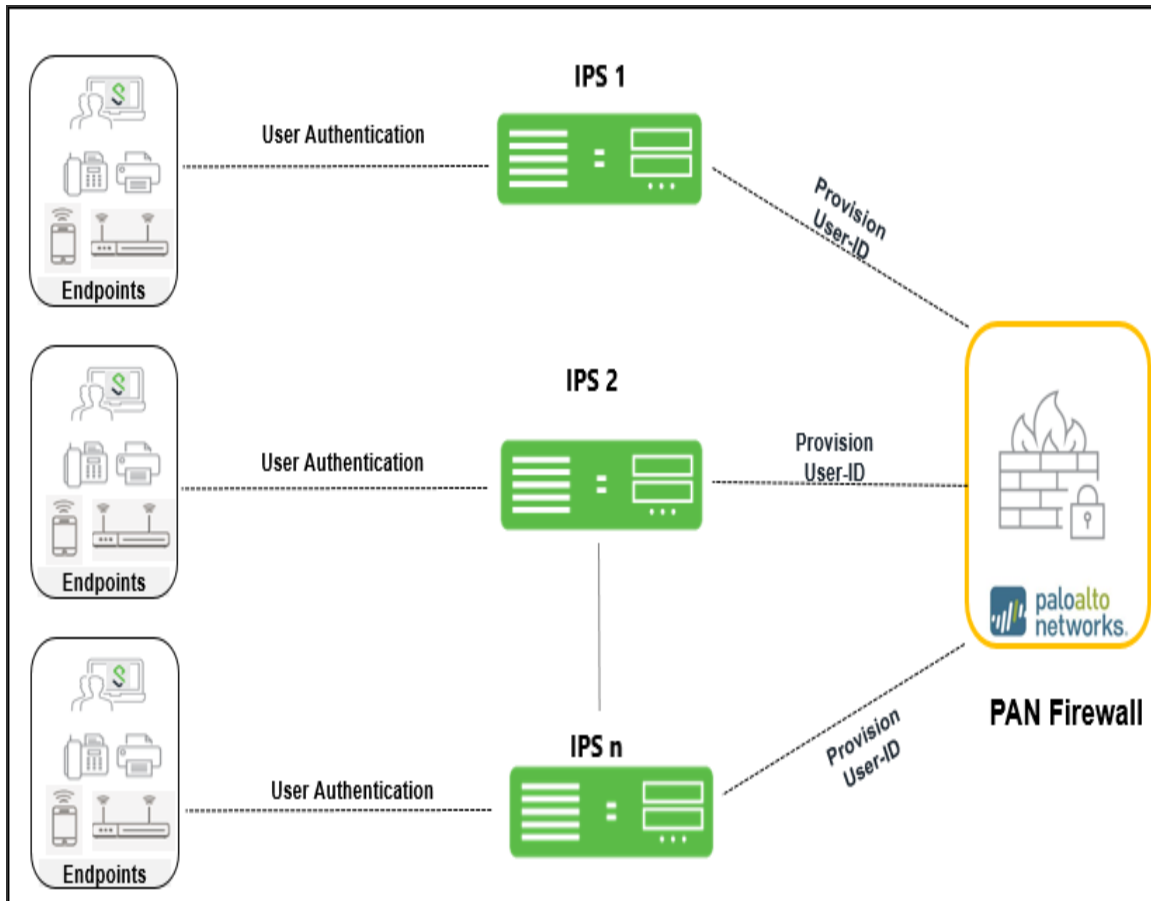

The authentication process is described below:

1. The endpoints connect to switch/WLAN and performs the layer 2 authentication with IPS.
2. IPS performs the layer 3 authentication and performs compliance check on the endpoint and detects for any unauthorized behavior.
3. IPS provisions the auth table entries on the PAN firewall.
4. IPS provisions the auth table with changes in role information if any on PAN firewall. The user role changes, which includes any unauthorized behavior are dynamically updated on the firewall. The access is based on roles, rather than only on source IP addresses.
5. The PAN firewall applies policies to allow or block user access to protected resources.

Deploying multiple IPS with PAN firewall

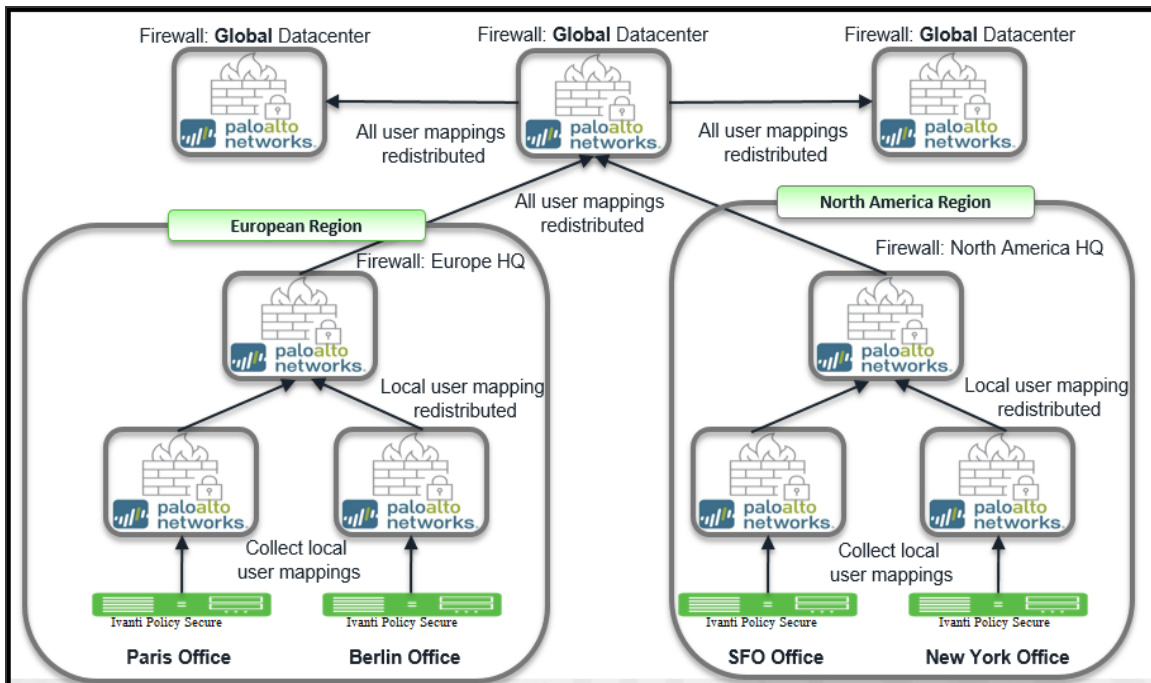

The deployment example describes an enterprise environment with multiple IPS servers where different users are authenticated using different IPS servers. For such deployments, multiple IPS servers can be configured to communicate with a single PAN firewall. The multiple IPS servers send user-ID entries to a single PAN firewall.

Deploying IPS with PAN firewall for a Large Enterprise

A large-scale enterprise network uses multiple firewalls to enforce policies. You can reduce the resources that the firewalls and information sources use in the querying process by configuring some firewalls to acquire mapping information. You can enable the firewall to enforce user based policies when users rely on local sources for authentication (for example, regional directory services) but need access to remote resources (for example, global data center applications).

The deployment example describes how a global datacenter resources is distributed across the branches and shared across the local offices. It also shows how you can organize the redistribution sequence in layers, where each layer has one or more firewalls. In this example, bottom-layer firewalls in local offices rely on IPS for authentication and then redistribute the mapping information to middle-layer firewalls in regional offices, which redistribute to one top-layer firewall in a global data center. The data center firewall redistributes the mapping information to other data center firewalls so that they can enforce global policies for all users.

Configuring IPS with PAN Firewall

This section covers the configuration of IPS for adding PAN firewall as an Infranet Enforcer.

Configuring PAN Infranet Enforcer in IPS

The IPS configuration requires defining a new Palo Alto Networks Firewall Infranet Enforcer instance on IPS and then fetching the API key from the firewall. The API key is used to communicate between the Palo Alto Networks firewall and IPS. The standard user authentication / authorization configurations such as Auth Table Mapping Policies should also be created and associated with the required roles.

To configure a Palo Alto Networks Firewall Infranet Enforcer in IPS:

1. Select **Endpoint Policy > Infranet Enforcer**.

[Infranet Enforcer](#) > [Infranet Enforcer Connection](#)

Infranet Enforcer Connection

[Connection](#) [Resource](#) [IPsec](#) [Auth Table Mapping](#) [IP Address Pools](#)

A connection policy specifies the connection between the Pulse Policy Secure and Infranet Enforcer.

[New Enforcer...](#) [Duplicate...](#) [Delete...](#)

10 records per page Search:

	Enforcer	Serial Numbers	Location Group	Platform	Version	FIPS	IP Address

2. Click **New Infranet Enforcer** and select Palo Alto Networks Firewall in the Platform drop down.

[Infranet Enforcer](#) > [Connection](#) > [New Infranet Enforcer](#)

New Infranet Enforcer

♥ [Infranet Enforcer](#)

Platform: Platform of this Infranet Enforcer.

* Name: Label to reference this Infranet Enforcer.

* IP Address: IP Address of this Infranet Enforcer

* API Key: [Get API Key](#) Auto-completed when you retrieve the API Key

Server Certificate Validation: ☐ Enable this option to verify the PAN firewall's certificate

[Save Changes](#)

* indicates required field

3. Enter the **Name** and **IP Address** of the Palo Alto Networks firewall and then click **Get API Key** which opens a new page:

4. Enter the **Admin Username** and **Admin Password** of the Palo Alto Networks firewall and then Click **Retrieve**. This enables IPS to fetch the API key of the firewall. Once the API key is retrieved, the page automatically redirects back to the New Infranet Enforcer page as shown above and updates the API Key Field.
See Configuring PAN Device Certificates for understanding the validation procedure.

5. Click **Save Changes**.

Configuring Auth Table Mapping Policies

An auth table entry consists of the user's name, a set of roles, and the IP address of the wired, wireless, or virtual adapter. An auth table mapping policy specifies which enforcer device can be used for each user role. These policies prevent the IPS from creating unnecessary auth table entries on all connected enforcer devices.

IPS's default configuration includes only one default auth table mapping policy. When the default auth table mapping policy is enabled, IPS pushes one auth table entry for each authenticated user to all Palo Alto Networks firewalls configured as Infranet Enforcers in IPS.

When you provision the authentication table from IPS to the firewall, ensure that the Profiler is configured with the Profiler Name and upload the FPDB, or do not configure the Profiler. If the Profiler is configured without uploading the FPDB, then the authentication table is not sent from IPS to Firewall.

To configure an Auth Table Mapping Policy:

1. Select **Endpoint Policy > Infranet Enforcer > Auth Table Mapping** and click **New Policy**.

Infranet Enforcer > Infranet Enforcer Auth Table Mapping Policies > AuthTablePolicy

AuthTablePolicy

General

* Name: AuthTablePolicy

Description: AuthTablePolicy

▼ Infranet Enforcer

Specify the Infranet Enforcer(s) to which this policy applies.

Available Enforcers: CHKPNT

Selected Enforcers: PAN

Save Changes Save as Copy

2. On the New Policy page:

- For Name, enter a name to label the auth table mapping policy.
- (Optional) For Description, enter a description.
- In the Enforcer section, specify the Infranet Enforcer firewall(s) to which you want to apply the auth table mapping policy.
- Under Enforcement Settings, Admin can enable **Provision only IP-User mapping to Palo Alto Networks Enforcer** to provision only the IP-user mapping information to Palo Alto Networks firewall.

This option is available only with Palo Alto Networks Enforcer.

If you are using group lookup (LDAP group from AD server) in the Palo Alto Networks security policy then enable "Provisioning only IP-User information to Palo Alto Networks Enforcer" in Ivanti Policy Secure to control resource access.

- In the Roles section, specify:
 - Policy applies to ALL roles-Select this option to apply the auth table mapping policy to all users.
 - Policy applies to SELECTED roles-Select this option to apply the auth table mapping policy only to users who are mapped to roles in the SELECTED roles list. You can add roles to this list from the available roles list.
 - Policy applies to all roles OTHER THAN those selected below-Select this option to apply the auth table mapping policy to all users except for those who map to the roles in the SELECTED roles list. You can add roles to this list from the available roles list.

- In the Action section, specify auth table mapping rules for the specified Infranet Enforcer.
 - Always Provision Auth Table-Select this option to automatically provision auth table entries for chosen roles on the specified Infranet Enforcer.
 - Provision Auth Table as Needed-Select this option to provision auth table entries only when a user with a chosen role attempts to access a resource behind the specified Infranet Enforcer. This option is greyed out for Palo Alto Networks Firewall Enforcers since it is not supported.
 - Never Provision Auth Table-Select this option to prevent chosen roles from accessing resources behind the specified Infranet Enforcer.
- 3. You must delete the Default Policy if you configure any custom auth table mapping policies. IPS's default configuration includes this default auth table mapping policy that allows all source IP endpoints to use all Infranet Enforcers.
- 4. If you created a vsys on a PAN Enforcer, enter the ID of the vsys in the vsys text box. To view the enforcers or vsys that are associated with each policy, select **Endpoint Policy > Infranet Enforcer > Auth Table Mapping**. If no VSYS ID is provided in VSYS textbox, then auth table will be provisioned to default VSYS in PAN firewall.
- 5. Enable **Provision Auth Table for one-to-one NAT deployment** to provision auth table entries for endpoints behind one-to-one NAT deployment. On enabling checkbox for "Provision Auth Table for one-to-one NAT deployment", admin will be redirected to a confirmation page. Click Enable button to enable the setting.
- 6. Click **Save Changes**.

Configuring Resource Access Policy

A resource access policy specifies which users are allowed or denied access to a set of protected resources. You can specify which users you want to allow or deny by choosing the roles for each resource access policy.

Resource Access Policy and IoT Policy Provisioning with Palo Alto Network's Firewall works only with default device name localhost.localdomain configuration.

Each Resource Access Policy is configured with single VSYS information. For a selected PAN firewall if resource access policy needs to be pushed to multiple VSYS, multiple Resource Access Policy need to be created that is one policy for each VSYS.

To configure Infranet Enforcer resource access policies:

1. Select **Endpoint Policy > Infranet Enforcer > Resource Access Policy** and click **New Policy**.

Infranet Enforcer > Infranet Enforcer Resource Access Policies > New Policy

New Policy

* Name:

Description:

▼ Infranet Enforcer

Platform: ☐ Juniper Enforcers ☒ Palo Alto Networks Firewall

Specify the Infranet Enforcer(s) to which this policy applies.
(Applicable for only Juniper and Palo Alto Networks Firewalls.)

Available Enforcers: (none)

Selected Enforcers: (all)

► Security Zones

▼ Service

Service:

▼ Resources

Specify the resources for which this policy applies, one per line.

Resources:

Examples:
Enter an IP address or Subnet or IP address range
192.168.80.150
192.168.80.0/24
10.0.0.0-10.255.255.255

IPv6 Resources:

Examples:
Enter an IPv6 address or an IPv6 address with its prefix
(Ex. 2001:db8:123:1::1 or 2001:db8:123:1::/64)

► Provision Settings

▼ Roles

☒ Policy applies to ALL roles
☐ Policy applies to SELECTED roles
☐ Policy applies to all roles OTHER THAN those selected below

Available roles:

Selected roles: (none)

▼ Actions

☒ Allow access
☐ Deny access

▼ Enforcer Options

VSYS:

NOTE: changes to this page will cause a slight interruption of service for Infranet Enforcer Resource Policies users.

* indicates required field

2. On the New Policy page:

- For Name, enter a name to label this Infranet Enforcer resource access policy.
- (Optional) For Description, enter a description.

For **Resources**, specify the protocol, IP address, network mask, and port of each resource (or range of addresses) for which this Infranet Enforcer resource access policy applies, one per line. Do not insert any spaces in your entries, or the policy may not be applied correctly.

For **IPv6 Resources**, specify the protocol, IPv6 address and port of each resource (or range of addresses) for which this Infranet Enforcer resource access policy applies, one per line. Do not insert any spaces in your entries, or the policy may not be applied correctly.

You cannot specify a host name in a resource access policy. You can specify only an IP address. You can use TCP, UDP, or ICMP.

- Under Infranet Enforcer, specify the Infranet Enforcer to which this policy applies by using Add.
- Specify one of the following in the Roles section:
 - **Policy applies to ALL roles**-To apply this Infranet Enforcer resource access policy to all users.
 - **Policy applies to SELECTED roles**-To apply this Infranet Enforcer resource access policy only to users who are mapped to roles in the Selected roles list. You must add roles to this list from the Available roles list.
 - **Policy applies to all roles other than those selected below**- To apply this Infranet Enforcer resource access policy to all users except those who map to the roles in the Selected roles list. You must add roles to this list from the Available roles list.
- In the Action section, specify whether you want to use this Infranet Enforcer resource access policy to allow or deny access to the specified resources.
- If you have created a vsys on PAN Enforcer, enter the ID of the vsys in the VSYS text box, if applicable.

If no VSYS ID is provided in VSYS textbox, then policy will be pushed to default VSYS in PAN firewall.

The **Infranet Enforcer > Resource Access Policy** page displays the Enforcers and/or vsys that are associated with each policy.

Infranet Enforcer > Infranet Enforcer Resource Access Policies

Configuring Palo Alto Networks Firewall

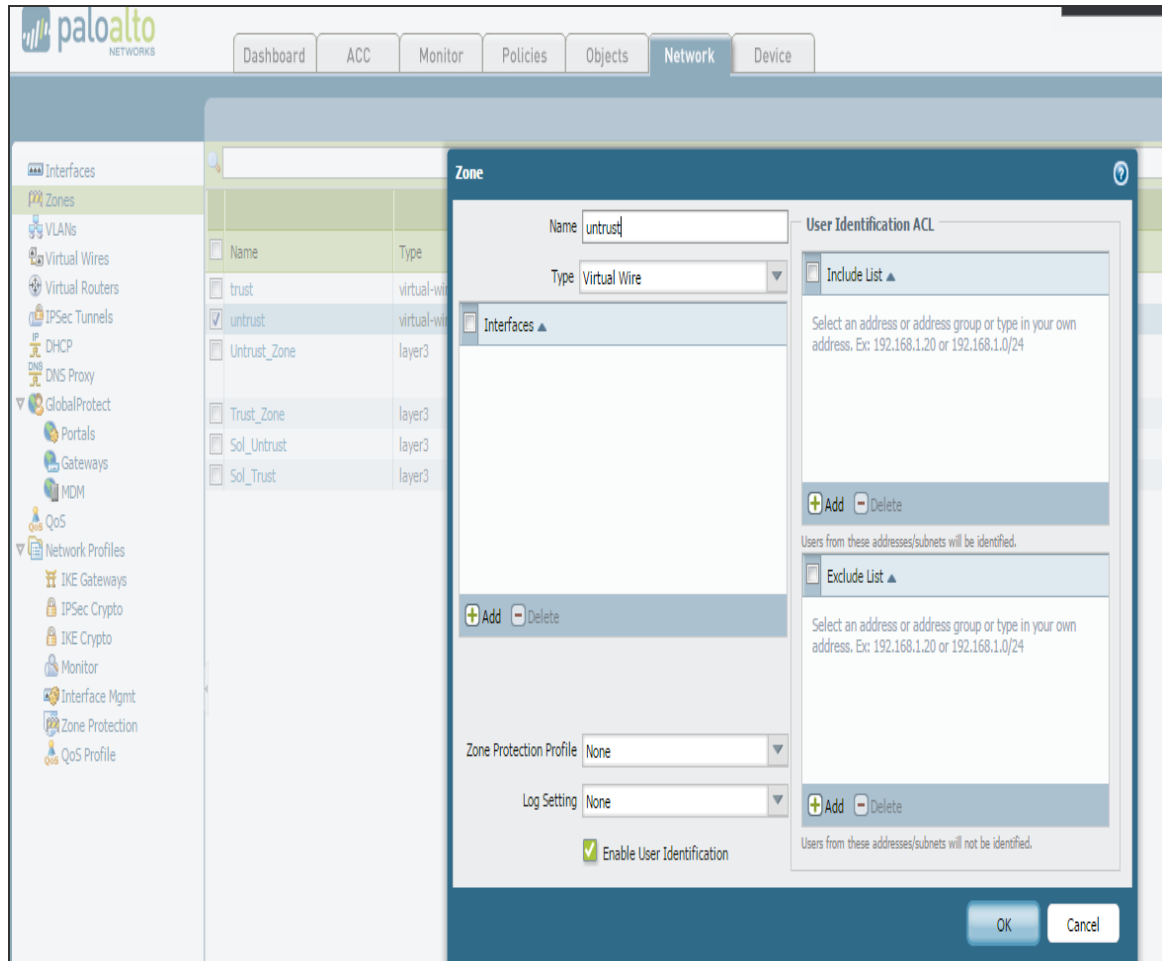

Palo Alto Networks firewall detects traffic from an endpoint that matches a configured security policy using the endpoint's auth table entry. It determines the role(s) associated with that user and allows or denies the traffic based on the actions configured in the security policy.

Configuring User Identification on Security Zones

Policy rules on the firewall use security zones to identify the source and the destination of the traffic. The data traffic flows freely within a zone and not between different zones until you define a security policy rule that allows it. To enable User-ID enforcement, you must enable User Identification on both inbound and outbound zones traversed by the end-user traffic.

To enable User Identification:

1. Select **Palo Alto Networks > Network > Zones**.
2. For each zone that serves as an inbound or outbound zone for enforced traffic, click the zone name (For example, trust, untrust, and so on).
3. Select **Enable User Identification** and click **OK**.

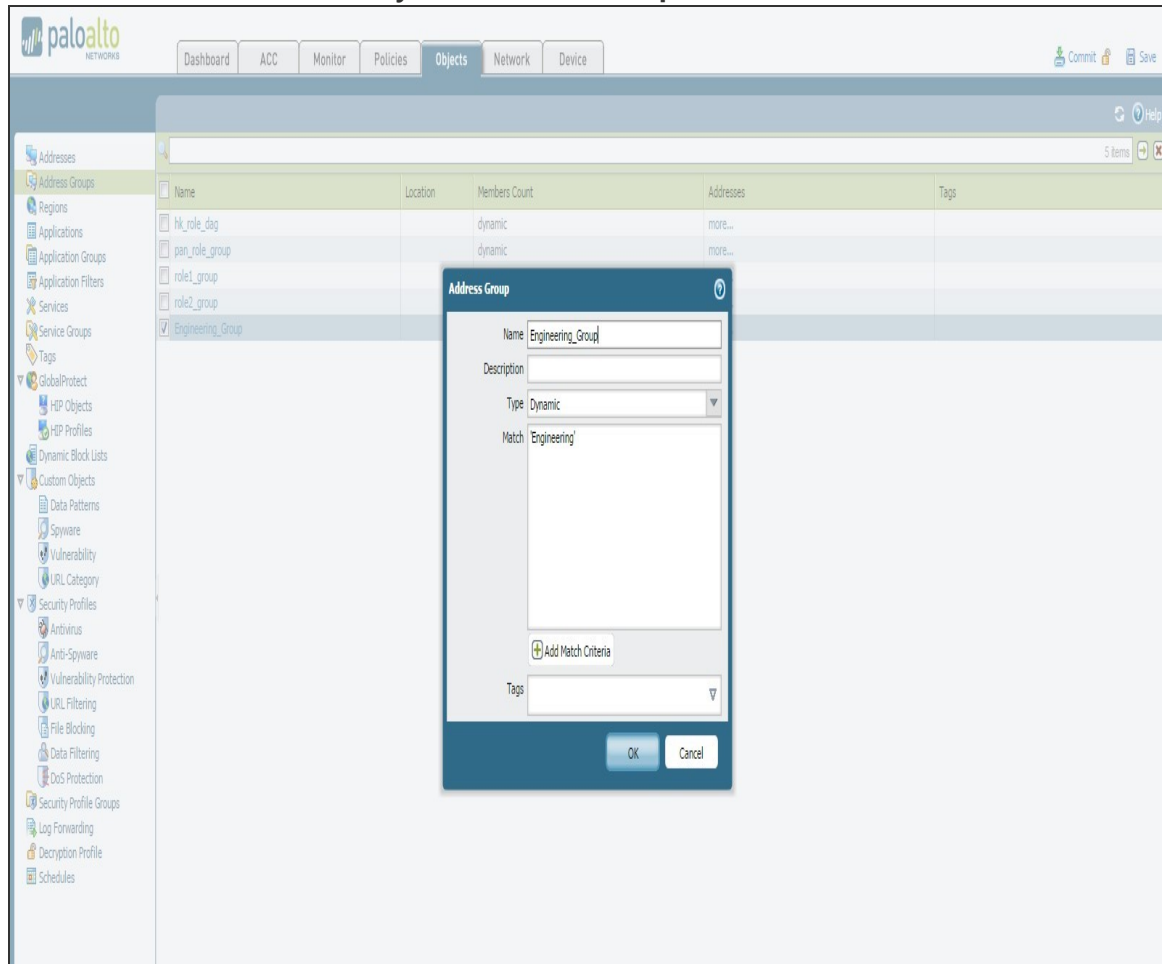

Provisioning of Resource Access Policies from IPS to the Palo Alto Networks Firewall Enforcer is not supported. You must configure the required security policies on the firewall.

Configuring Dynamic Address Groups

Dynamic address groups allow you to create policy that automatically adapts to changes-adds, moves, or deletions of servers. It also enables the flexibility to apply different rules to the same server based on its role on the network or the different kinds of traffic it processes.

To configure a dynamic address group:

1. Select **Palo Alto Networks > Objects > Address Groups**.

2. Click **Add** and enter a Name and a Description for the address group.
3. Select Type as **Dynamic**. Define the match criteria. You can select dynamic and static tags as the match criteria to populate the members of the group.
4. Enter the role name of the users. The role name in the Match section should match the roles that are configured in IPS.
5. Click **OK**.

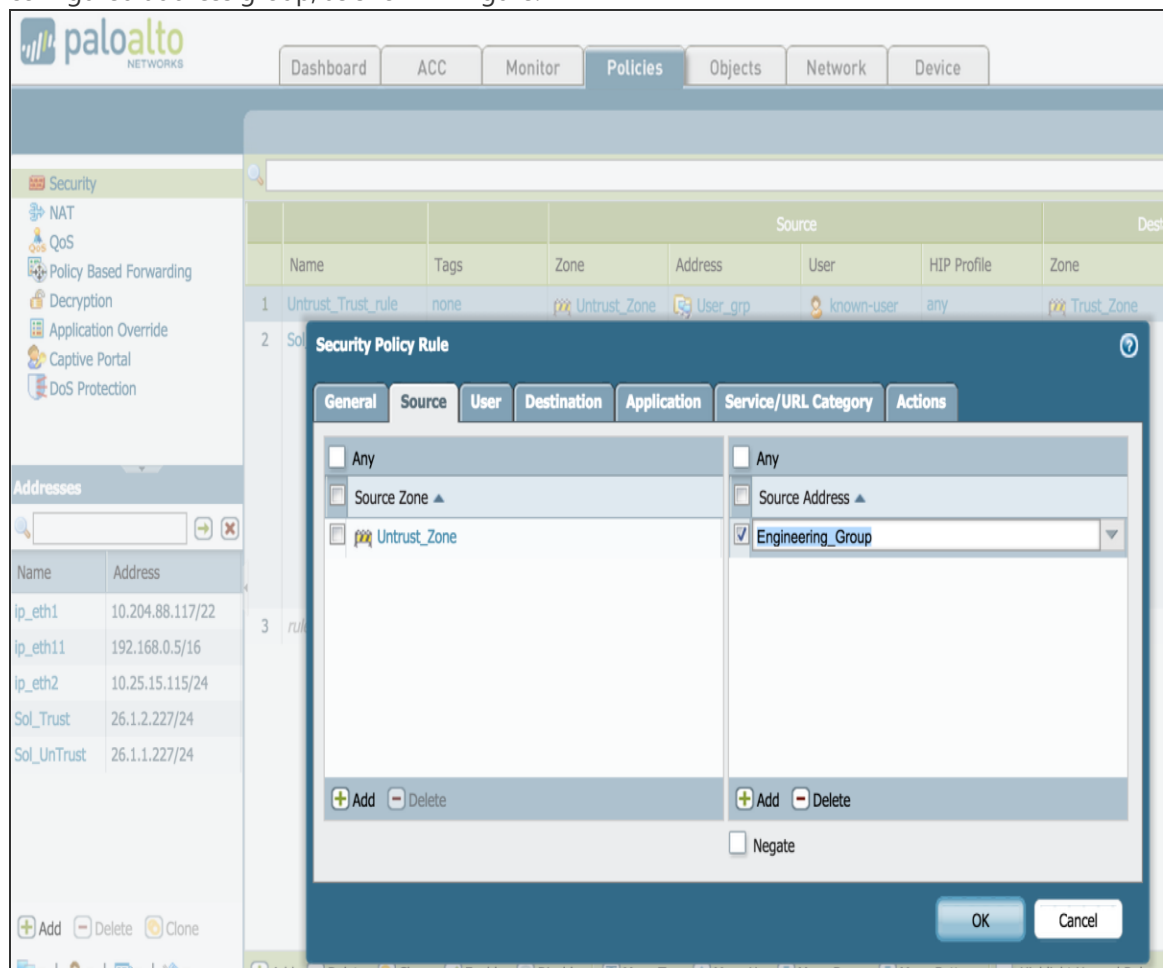

Dynamic discovery of users and their roles is not supported on the Palo Alto Networks firewall.

Configuring Security Policies

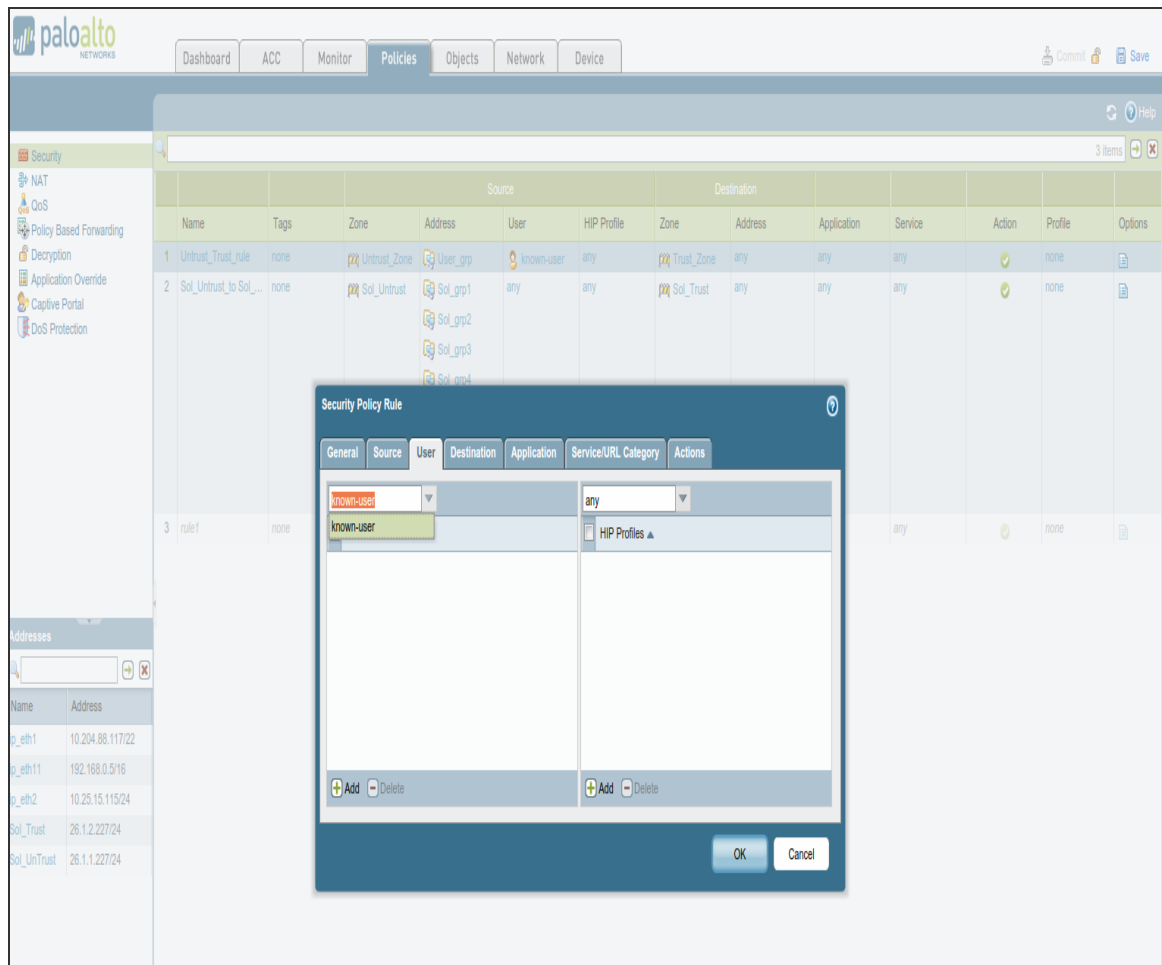

Security policies protect network assets from threats and disruptions and aid in optimally allocating network resources for enhancing productivity and efficiency in business processes. On the Palo Alto Networks firewall, security policies determine whether to block or allow a session based on traffic attributes such as the source and destination security zone, the source and destination IP address, the application, user, and the service.

To configure security policies associated with dynamic address groups:

1. Select **Palo Alto Networks > Policies > Security**.
2. Click Add to create a new security policy rule. In the Source Address tab, select the previously-configured address group, as shown in figure.

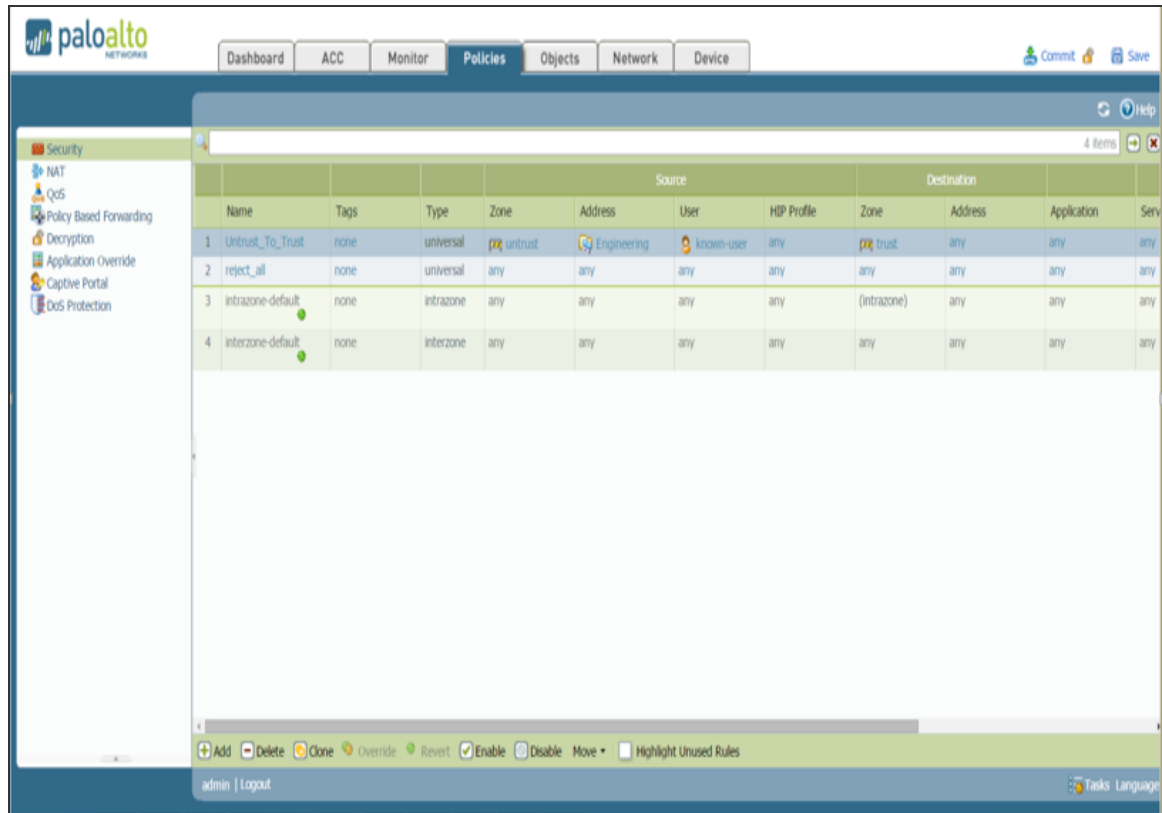

3. In the User tab, enable **known-user**.

When the **known-user** is enabled, the resource access is revoked immediately once the user disconnects from IPS.

4. Configure the other options to meet your security requirements. Traffic from the endpoint is allowed or blocked based on the action chosen under the Action tab.

5. Click **Commit** to complete the configuration. The completed security configuration on the Palo Alto Networks firewall is shown below.

Configuring PAN Device Certificates

PAN device certificate validation enhances the security between IPS and the PAN device. It allows IPS to verify whether the server certificate is from a trusted source. This topic describes how to configure the IPS for validating device certificates, creating certificates on PAN, and checking the validity of the certificate.

Creating a Certificate Signing Request (PAN 6.0 and later)

To create a Certificate Signing Request (CSR) for sending to public third-party Certificate Authority (like Verisign, Globalsign, Entrust, and so on). For more information, see

<https://www.paloaltonetworks.com/documentation/60/pan-os/pan-os/certificate-management/obtain-certificates>

1. Select **Device > Certificate Management > Certificates > Device Certificates**.

Generate Certificate

Certificate Name: PANcertificate

Common Name: www.example.com
IP or FQDN to appear on the certificate

Signed By: External Authority (CSR) ☐ Certificate Authority

OCSP Responder:

Cryptographic Settings

Algorithm: RSA
Number of Bits: 2048
Digest: sha256
Expiration (days): 365

Certificate Attributes

Type	Value
<input checked="" type="checkbox"/> Country	DE

+ Add - Delete

Generate Cancel

2. Enter a **Certificate Name** (save this name for later).
3. In the Common Name field, enter the IP address of the interface where you will configure the service that will use this certificate.
4. Select the **Certificate Authority (CA)** check box for self-signed root CA certificate. Exporting the CSR and Importing the Signed Certificate are not applicable for self-signed certificates.

Uncheck the **Certificate Authority** check box if you are using enterprise CA, or trusted third-party CA certificates.

5. Complete the remaining details such as Country, Organization, and so on. Check with the Certificate Authority (CA) about their requirements for Certificate Attribute formatting and criteria.
6. Click **Generate**.

Ensure that the SSL/TLS service profile is enabled while creating the server certificate.

Exporting the CSR and Importing the Signed Request

Once the CSR is created, you must export the CSR to a third-party CA for signature.

To export the CSR:

1. Click the check box next to the Certificate Name.
2. Click **Export** and save the file.
3. Send the exported CSR to a third-party Certificate Authority. The CA will respond with a signed certificate.

Once the CA responds with the signed certificate, you must import the signed certificate from the certificate authority.

To import the signed certificate:

1. Note the name, including capitalization, of the certificate to import. (This must match the CSR request from above.)
2. Click **Import**.
3. In the Import Certificate dialog, type the name of the pending certificate. It must match exactly.
4. Go to the signed certificate received from the Certificate Authority and click OK.
5. Do not click the **Import Private Key** check box.
6. Depending on the certificate authority used, it may be necessary to chain the intermediate certificate with the server certificate and import it before completing this step.
7. Click **OK**.

Importing the Certificate on IPS

You can use the Trusted Server CAs page to import the trusted root certificate.

To configure device certificate verification:

1. Select **System > Trusted Server CAs > Import Trusted Server CA**.
2. Click **Browse** and select the certificate file.
3. Click **Import Certificate**. The Trusted Server CA page appears.
4. Verify if the certificate is imported successfully and click **Done**.
5. Click **Configuration > Certificates > Trusted Server CAs** and verify that the certificate is from a trusted source.

Adding PAN Device to IPS

For complete information on configuration, See [Configuring PAN Infranet Enforcer in IPS](#).

If the server certificate is not valid the user will see the following error message. Error: Failed to Retrieve API Key. Peer Certificate cannot be authenticated with known CA certificates.

Troubleshooting

You can use the following CLI commands on the Palo Alto Networks firewall for troubleshooting:

- *show user ip-user-mapping all*- Displays the table of user identities mapped to IP addresses.
- *show object registered-address all* - Displays the table of addresses with user information associated.

For identity management using Palo Alto Networks firewall only minimum Admin role permissions are sufficient. Ensure that the XML API rights on the Palo Alto Networks UI is enabled as shown in the below screenshot.

The screenshot shows the 'Admin Role Profile' configuration window. At the top, the 'Name' field is set to 'xmladmin' and the 'Description' field is empty. Below these fields are three tabs: 'Web UI', 'XML API', and 'Command Line'. The 'Web UI' tab is selected, displaying a list of permissions with green checkmarks indicating they are enabled. The permissions listed are: Report, Log, Configuration, Operational Requests, Commit, User-ID Agent, Export, and Import. At the bottom of the list, there is a legend: a green checkmark for 'Enable', a lock icon for 'Read Only', and a red X for 'Disable'. The 'OK' and 'Cancel' buttons are located at the bottom right of the window.

Permission	Status
Report	Enable
Log	Enable
Configuration	Enable
Operational Requests	Enable
Commit	Enable
User-ID Agent	Enable
Export	Enable
Import	Enable

Legend: Enable Read Only Disable

Admin can choose to disable other options from the Web UI tab of the Palo Alto Networks UI as per the security requirement.

The screenshot shows the 'Admin Role Profile' configuration window. At the top, the 'Name' field is set to 'xmladmin' and the 'Description' field is empty. Below these fields are three tabs: 'Web UI', 'XML API', and 'Command Line'. The 'Web UI' tab is selected, displaying a list of features with status icons (green check for Enable, blue lock for Read Only, red X for Disable). All listed features are disabled. The legend at the bottom indicates: Legend: Enable Read Only Disable. The 'OK' and 'Cancel' buttons are at the bottom right.

Feature	Status
Dashboard	Disable
ACC	Disable
Monitor	Disable
Policies	Disable
Objects	Disable
Network	Disable
Device	Disable
Privacy	Disable
Validate	Disable
Save	Disable
Commit	Disable
Tasks	Disable
Global	Disable

Unsupported Features

The following features are not supported:

- Captive portal
- IPsec Enforcement
- Dynamic Auth Table Allocation

For federated access across multiple policy servers / firewall enforcers federated single sign-on for Ivanti Connect Secure tunneled traffic, see [Provisioning IPS sessions to PAN/Check Point/FortiGate Firewall](#)

For information on Alert based Admission Control, see Admission Control using Palo Alto Networks Firewall

Enforcement using FortiGate Firewall

Overview

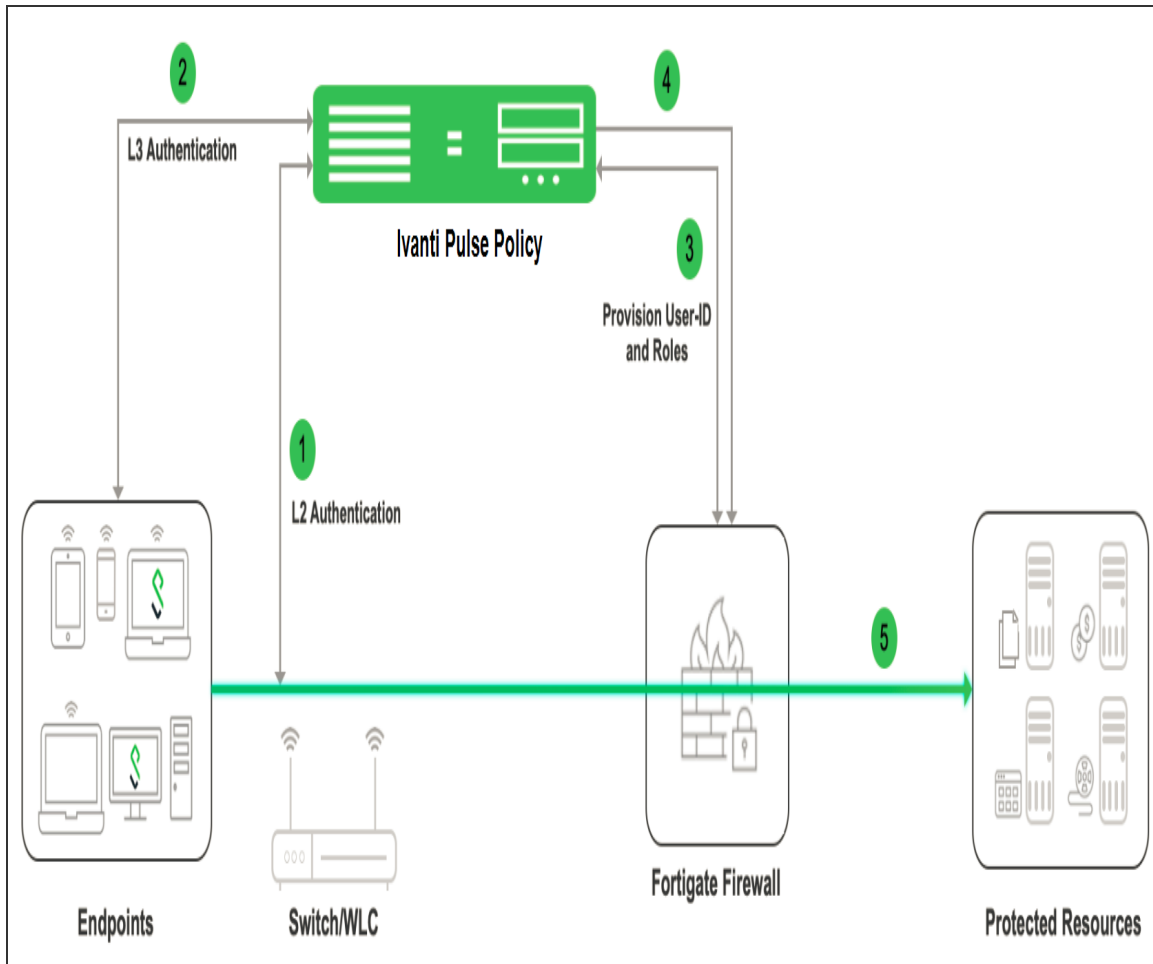

This chapter covers the FortiGate firewall integration with IPS using RADIUS accounting messages. FortiGate Firewall "SSO using RADIUS accounting records" feature allows FortiGate to receive user and group information details using RADIUS accounting messages.

FortiGate firewall can authenticate users transparently who have already authenticated on an external RADIUS server. The security policy applies the appropriate profiles based on the user group to which the user belongs. RADIUS SSO is relatively simple because the FortiGate unit does not interact with the RADIUS server, it only monitors RADIUS accounting records that the server forwards (originating from the RADIUS client, i.e Ivanti Policy Secure). These records include the user's IP address, user group and user name.

FortiGate needs to know the user's endpoint identifier (usually IP address) and RADIUS user group.

Deployment of IPS using FortiGate Firewall

This section describes the integration of IPS with FortiGate firewall.

The authentication process is described below:

1. The user is authenticated on IPS after validating the host check policy to ensure that the endpoints meets the corporate policy.
2. IPS learns the endpoint IP using RADIUS accounting(L2) or L3 connection.
3. The User Id, IP address and role(s) are provisioned to the firewall.
4. Ivanti Policy Secure shares the User Id, IP address and role information with FortiGate firewall in the form of a RADIUS accounting packet.
5. The FortiGate firewall maps the user to a specific security policy and then provides the required access.

If multiple firewall devices are configured, then the user's information will be provisioned to all the devices. The user's information will be sent to the firewall only if user's role requires session to be provisioned.

Configuring IPS with FortiGate Firewall

To configure FortiGate firewall:

1. Select **Endpoint Policy > Infranet Enforcer**.
2. Click New Infranet Enforcer and select FortiGate Firewall in the Platform drop down.

Infranet Enforcer > Connection > New Infranet Enforcer

New Infranet Enforcer

♥ Infranet Enforcer

Platform: FortiGate Firewall Platform of this Infranet Enforcer.

* Name: fortigate900D Label to reference this Infranet Enforcer.

* IP Address: IP Address of this Infranet Enforcer

* Shared Secret: Pre-Shared Secret

* Accounting Port: 1813 Port used for RADIUS accounting

Save Changes

* indicates required field

3. Enter the name of the Infranet Enforcer in the Name box.
4. Enter the IP address of FortiGate Firewall.
5. Enter the shared secret.
6. Enter the port number used for RADIUS accounting.

7. Click Save Changes. You must create security policies on the FortiGate firewall for traffic enforcement.
8. Check the Status > Overview page for checking the status of the connection.

The screenshot displays the 'System Status Overview' page in the FortiGate web interface. The page is divided into several sections:

- Navigation Tabs:** Activity, Overview (selected), Active Users, Device Profiles, Behavioral Analytics, Admin Notification.
- Filters:** Timeframe: 1 hour, Refresh: 60 seconds (Minimum 60 seconds), Select list of graphs, Charts Per Row: 3, and a Save Changes button.
- Appliance Details:**
 - Logging Disk: 0% Full
 - Licenses: Max Licensed Users: 20000
 - Total Users: User Licenses: 1, MAC Address Users: 0, Total Signed-In Users: 1
 - Member Status: NodeA, NodeB* (Node currently used)
 - Enforcer Status: fortigate9000
- System Metrics (Charts):**
 - System Version: 9.1R3 (build 2002)
 - Licenses used: 1 of 20000
 - Total Users: 1
 - Logging Disk: 0%
- Critical Events:** Timeframe: 1 days (1-30), Save button, (Note: Maximum 100 events), Last Updated: 2019-09-16 10:41:13 PM. A table with columns Timestamp and Message is shown, containing the message 'There are no critical messages to display'.

Configuring Auth Table Mapping Policy

When you provision the authentication table from IPS to the firewall, ensure that the Profiler is configured with the Profiler Name and upload the FPDB, or do not configure the Profiler. If the Profiler is configured without uploading the FPDB, then the authentication table is not sent from IPS to Firewall.

To configure auth table mapping policies:

1. Select **Endpoint Policy > Infranet Enforcer > Auth Table Mapping**.
2. Click **New Policy**.
3. Enter a name to label this auth table mapping policy.
4. Select FortiGate as an enforcer in the Enforcer section, specify the Infranet Enforcer device(s) to which you want to apply this auth table mapping policy.
5. In the Action section, specify auth table mapping rules for the specified Infranet Enforcer.
6. Click **Save Changes**.

Configuring FortiGate Firewall

The FortiGate firewall detects traffic from an endpoint that matches a configured security policy using IPS RSSO record. It determines the role(s) associated with that user, and allows or denies the traffic based on the actions configured in the security policy.

To configure FortiGate firewall:

1. Select **System > Network > Interfaces**[datainterface] and enable **RADIUS Accounting** to allow the interfaces to listen for RADIUS Accounting Messages.

2. Select **Fabric Connector > Create New**, under **SSO/Identity** select **RADIUS Single Sign-On Agent**.

- Name: Enter a name for the entry
- Enter the RADIUS shared secret, which matches with IPS.
- Click **OK**.

The screenshot displays the FortiGate 900D web interface. The top header shows the device name 'FortiGate 900D' and the ID 'FG900D3917800553'. The left sidebar contains a navigation menu with options: Dashboard, Security Fabric (expanded), Physical Topology, Logical Topology, Security Rating, Automation, Settings, Fabric Connectors (selected), FortiView, Network, System, Policy & Objects, Security Profiles, VPN, User & Device, WiFi & Switch Controller, Log & Report, and Monitor. The main content area is titled 'Edit Fabric Connector' and shows the 'SSO/Identity' section. A 'RADIUS Single Sign-On Agent' is listed with a green checkmark icon. Below this, the 'Connector Settings' section is visible, containing the following fields: 'Name' (PPS RSSO Agent), 'Use RADIUS Shared Secret' (checked), and 'Send RADIUS Responses' (checked). The 'Use RADIUS Shared Secret' field is masked with dots. At the bottom right, there are 'OK' and 'Cancel' buttons.

3. Create matching User groups. Select **User & Device > User Groups**. Click create New and enter the following data:

- Name- Enter the name of the group. This name will appear in the firewall policy.
- Type- Select RADIUS Single Sign-On as type.
- RADIUS Attribute Value- Enter the User Role created on IPS to match the User Group in FortiGate.
- Click **OK**.

User Definition

User Groups ☆

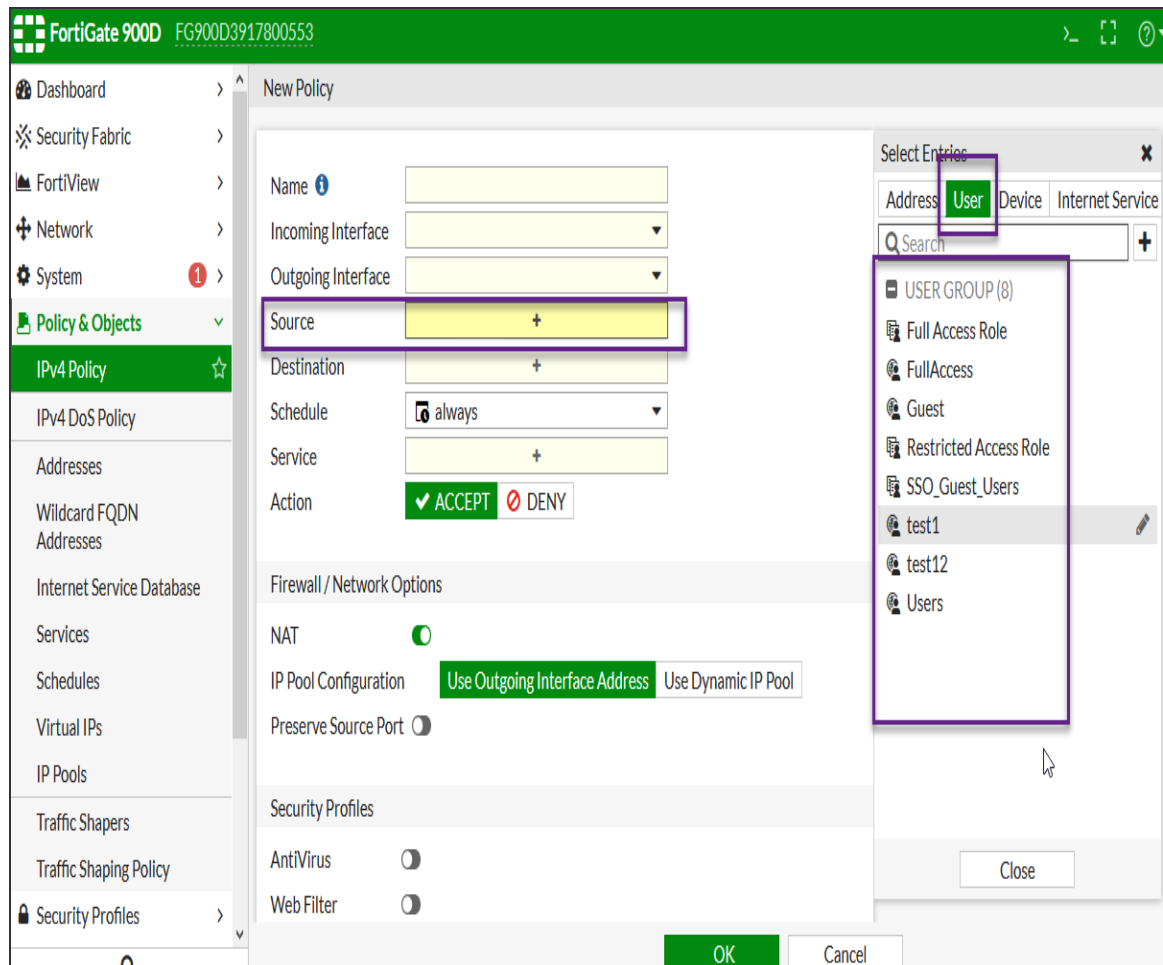

Name: Users

Type: Firewall, Fortinet Single Sign-On (FSSO), **RADIUS Single Sign-On (RSSO)**

RADIUS Attribute Value: Users (This value matches the value from the RADIUS Accounting-Start attribute)

OK Cancel

4. Create a firewall policy to use the IPS enforcement groups just created. Select **Policy & Objects** > **IPv4 Policy**. Click Create New and create the policy based on the resource access restrictions to be enforced.

5. Disable overriding of the roles on FortiGate firewall when the same user logs in with a different device. The default behavior is to override the role information with the latest role received from IPS.

For example, if a same user login's to IPS from different devices (mobile/laptop) with different roles (Employee/Guest). Fortigate firewall overrides the role information with the latest role by default. To disable overriding with the latest roles "set sso-attribute-value-override disable".

```
config user radius
edit <My_Rsso>
set rsso enable
set sso-attribute-value-override enable/disable // Enable/Disable
override old attribute value with new value for the same endpoint.
end
```

Reports and Logging

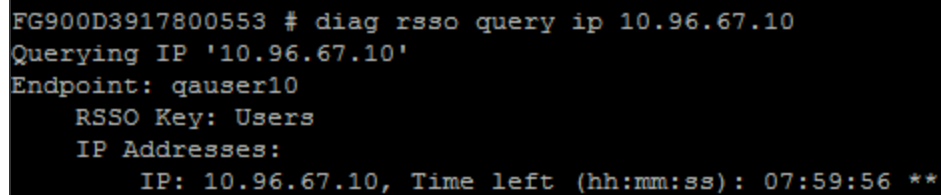

1. You can monitor the RSSO Sessions on FortiGate firewall from CLI or GUI:

Using the FortiGate CLI, type:

```
diag rsso query ip <Ip-Address>
```

```
diag rsso query rsso-key
```

*Queries the RSSO database.

```
FG900D3917800553 # diag rsso query ip 10.96.67.10
Querying IP '10.96.67.10'
Endpoint: gauser10
  RSSO Key: Users
  IP Addresses:
    IP: 10.96.67.10, Time left (hh:mm:ss): 07:59:56 **
```

2. Select **Monitor > Firewall user Monitor**. The list shows all the identity records.

Identity Based Enforcement using FortiGate Products

Overview

IPS integration with the FortiGate firewall provides enhanced identity enabled enforcement with backend authentication and comprehensive compliance checks. This section describes the procedure to integrate IPS with FortiGate firewall using FortiAuthenticator, which acts as a syslog server. The FortiAuthenticator receives the syslog messages from IPS and then creates Fortinet Single Sign-on (FSSO) record which is then shared with FortiGate firewall. The firewall uses the FSSO information to either allow or block traffic based on the configured policy.

Deployment of IPS using FortiAuthenticator and FortiGate Firewall

This section describes the integration of IPS with FortiAuthenticator and FortiGate firewall. The IPS and Fortinet solution provides functionality for enforcing security policies on a per user and role basis.

The authentication process is described below:

1. The user is authenticated on IPS after validating the host check policy to ensure that the endpoints meet the corporate policy.
2. The syslog sessions are exported to FortiAuthenticator.
3. Identity information is parsed from the syslog message and is used to create an IP address to username mapping file within FortiAuthenticator. This information is shared with FortiGate firewall in the form of a FSSO record.
4. The FortiGate firewall maps the user to a specific resource access policy and then provides the required access.

Configuring IPS with FortiAuthenticator

The IPS configuration requires defining the FortiAuthenticator as the syslog server on IPS. The Syslog sever uses the filter created in the User Access Log Filters for receiving and parsing the logs.

Creating Custom Filter for User Access Logs

To create a custom filter in IPS:

1. Select **System > Log/Monitoring > User Access > Filters**.
2. Click **New Filter**.
3. Enter the filter name.
4. Under Export Format, select **WELF**.
5. Click **Save** to save the filter.

The screenshot shows the 'New Log filter' configuration page in the FortiGate GUI. The breadcrumb trail is 'Log/Monitoring > User Access > Filters > New Log filter'. The page title is 'New Log filter'. There are tabs for 'Events', 'User Access' (selected), 'Admin Access', 'Sensors', 'Client Logs', 'SNMP', 'Statistics', and 'Advanced Settings'. Below the tabs, there are sub-tabs for 'Log', 'Settings', and 'Filters' (selected). The 'Filter' section contains a 'Filter Name' field with the value 'FSSO' and a checkbox labeled 'Make default for syslog and archiving filter selection'. Below this is a 'Query' section with a green arrow icon. The 'Export Format' section shows four radio buttons: 'Standard', 'WELF' (selected), 'W3C', and 'Custom'. A text area below the radio buttons contains the following log format string: `id=firewall time="%date% %time%" pri=%syslogcode%
fw=%localip% vpn=%node% user=%user% realm="%realm%"
roles="%role%" proto=%protocol% src=%sourceip%
dst=%remoteip% dstname=%remotehost% type=vpn`. At the bottom of the page are 'Save' and 'Cancel' buttons.

Editing the Custom Filter

To edit the custom created filter:

1. From the **Log Filters** screen, click the filter name and edit the filter.
2. Under **Export Format**, select **Custom** format.
3. Edit the **ID** with the filter name. For example, id=FSSO.
4. Click **Save**.

Configuring Syslog Server

You can configure IPS to send logs to FortiAuthenticator syslog server.

To configure the syslog server:

1. Select **System > Log/Monitoring > User Access > Settings Policy** and click **New Policy**.
2. Under **Select Events to Log**, retain the default settings.
3. Under **Syslog Servers**, create a new Syslog server with the following details:
 - Server name/IP- Enter the fully qualified domain name or the IP address for the syslog server (FortiAutheticator).
 - Facility- Select **LOCAL0** as the facility level.
 - Type- Select **UDP** as the connection type.
 - Filter- Select the custom created filter format.
4. Click **Add** and then click **Save Changes**.

You must add FortiAuthenticator as a syslog server in all the nodes in a clustering environment.

Configuring FortiAuthenticator

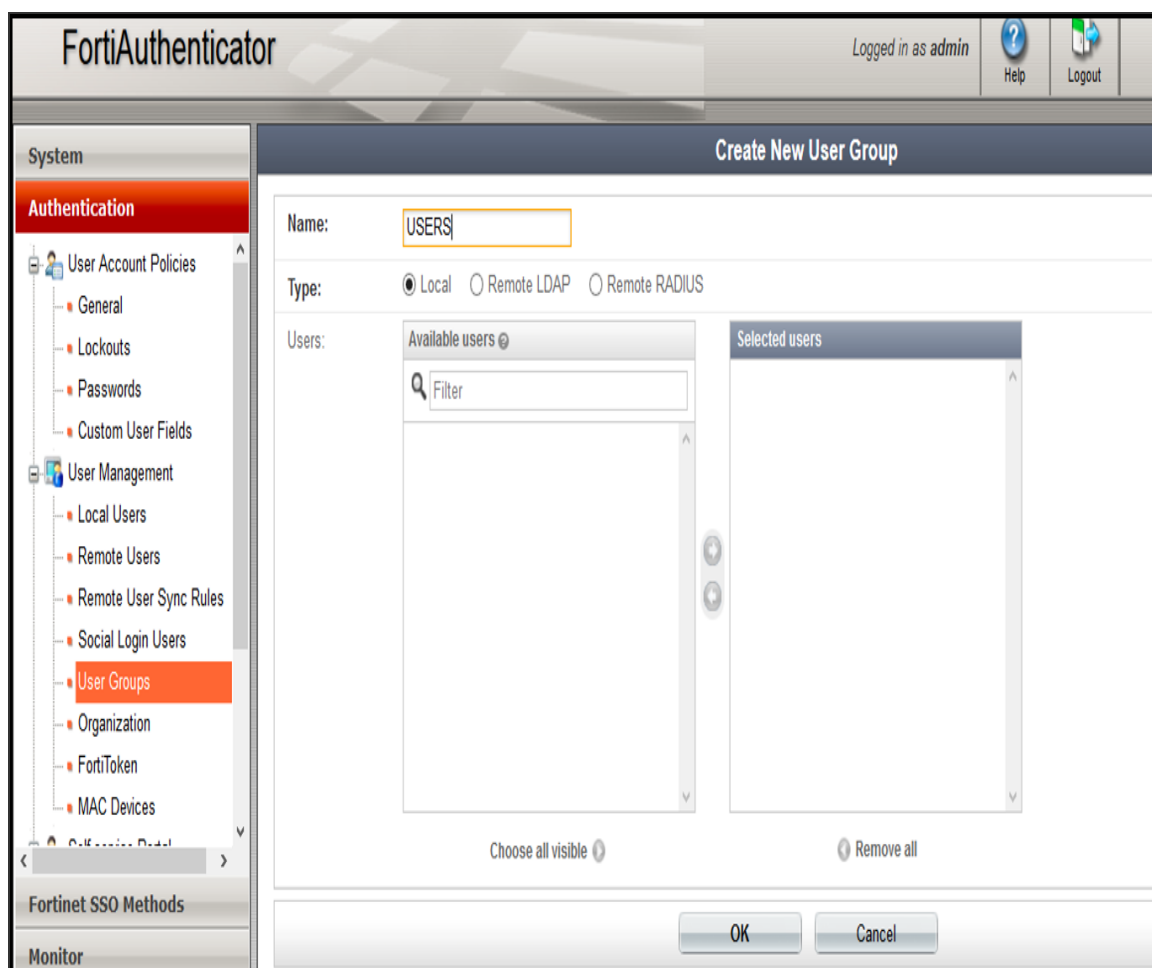

You must add IPS as a syslog source in FortiAuthenticator to parse the information.

Prerequisite:

- Ensure that the FortiAuthenticator instance is communicating on the network and is reachable from the IPS appliance's management interface.
- Select **System > Network > Interfaces**, select the port and enable the FortiGate FSSO, FortiClient FSSO and Syslog services on FortiAuthenticator interface, which communicates with IPS and FortiGate firewall.

To configure FortiAuthenticator:

1. Create a Local user group with the names which matches the name IPS will send as the 'Group=' value in your Syslog messages. Select **Authentication > User Management > User Groups** and click Create New. Create the groups with the following data:
 - Name- Enter the same names, which is received from IPS, For example, Users.
 - Type- Select Local as type.
 - Click **OK**.

2. Create a syslog matching rule. Select **Fortinet SSO methods > SSO > Syslog Sources**. In the upper right corner, from the 'View' drop down choose matching rules and click **Create New** and give the following data:

- **Name:** Enter the name for the syslog Rule.
- **Trigger:** Enter the filter name created in IPS. For example, id=FSSO
- **Auth Type Indicators:** Enter strings to differentiate between the types of user activities. For example, **Logon:** AUT24803
- **Update:** AUT23524
- **Logoff:** AUT22673
- **Username field:** Define the semantics of the username field, where {{user}} indicates where the username is extracted from. For example: user= {{: username}}
- **Client IP field:** Define the semantics of the client IP address. For example, src={{:client_ip}}
- **Group field:** Define the semantics of the group. For example: roles=" {{: group}}"

There is a trailing space after the User, IP, and Group fields. The parser treats the trailing space as an ending character after the variable portion of the field. The parsing fails if the trailing space is omitted.

- **Group List Separator:** SSO syslog feed can parse multiple groups if the names are separated by a plus (+) symbol or a comma (,). Use the Group list separator to specify the separator.
- **Test Rule:** Enter a sample log message into the text box, then select Test to test that the desired fields are correctly extracted.

3. Click **OK** to add the new matching rule.

Group list separator:

Test Rule

Test the matching rule above by entering a sample log line to parse below.

Enter a sample log line

For the Logon and Logoff indicators, the data specified will vary depending on the installation and depending on your syslog message contents. In this example, when a user logs in the message ID created is AUT24414 and is considered as a Logon event on FortiAuthenticator. When the role change happens as part of periodic host check updates, the message ID created by IPS is AUT23524. A sign-out event is considered a 'Logoff' event on FortiAuthenticator, and the identity is removed from the user group, thus, failing to match policy.

4. Create a Syslog source, Select Fortinet SSO methods > SSO > Syslog Sources. In the upper right corner, from the 'View' drop down choose Syslog Source and click Create New and provide the following data:
- Name- Enter a name for the source
 - IP address- Enter the IP address of IPS server
 - Matching rule- Select the requisite matching rule created above.
 - SSO user type- Select External as the user type.

The screenshot shows the FortiAuthenticator web interface. The left sidebar contains a tree view with categories: System, Authentication, and Fortinet SSO Methods. Under Fortinet SSO Methods, the following items are listed: SSO, General, Portal Services, Fine-grained Controls, SSO Users, SSO Groups, Domain Controllers, RADIUS Accounting, Syslog Sources (highlighted), FortiGate Filtering, IP Filtering Rules, Tiered Architecture, and Accounting Proxy. The main content area is titled 'Create New Syslog Source'. It contains the following fields:

- Name: A text box containing 'Pulsesecure'.
- IP address: A text box containing 'x.x.x.x'.
- Matching rule: A dropdown menu with 'Pulse' selected.
- SSO user type: Three radio buttons labeled 'External', 'Local users', and 'Remote users'. 'External' is selected.
- Below the radio buttons is a dropdown menu with '[Please Select]'.

At the bottom right of the form are 'OK' and 'Cancel' buttons. The top right of the interface shows 'Logged in as admin' and links for 'Help' and 'Logout'.

You must add all the cluster node IP's (not cluster VIP's) in the FortiAuthenticator when using a IPS cluster setup.

Configuring FortiGate Firewall

The FortiGate firewall detects traffic from an endpoint that matches a configured security policy using the FortiAuthenticator FSSO record. It determines the role(s) associated with that user, and allows or denies the traffic based on the actions configured in the security policy.

To configure FortiGate firewall:

1. (Applies to Release 6.0.*) Create the FortiAuthenticator as an FSSO agent in the FortiGate Firewall. Select **Fabric Connector** > **Create New**, under SSO/Identity select **Fortinet Single Sign-On** Agent.
 - Name: Enter a name for the entry
 - Primary FSSO Agent: Enter the IP address of the FortiAuthenticator appliance, and the password* used to communicate with it.
 - Click **Apply & Refresh** to test your configuration. If correct, the users /groups area will automatically populate

Apply & Refresh OK Cancel

(Applies to Release 5.6.*) Create the FortiAuthenticator as an FSSO agent in the FortiGate Firewall. Select **User & Device** > **Single Sign-On** and click Create **New** and enter the following data.

- Type: Fortinet Single-Sign-On Agent
- Name: Enter a name for the entry
- Primary Agent IP/Name: Enter the IP address of the FortiAuthenticator appliance, and the password* used to communicate with it.

*This is the same as the secret key configured on FortiAuthenticator in the Fortinet SSO Methods > General section.

- Click **Apply & Refresh** to test your configuration. If correct, the users /groups area will automatically populate.

The screenshot displays the FortiGate VM64 web interface. On the left, a navigation menu is visible with categories like Dashboard, FortiView, Network, System, Policy & Objects, Security Profiles, VPN, User & Device, Single Sign-On, LDAP Servers, RADIUS Servers, Authentication Settings, FortiTokens, WFI & Switch Controller, Log & Report, and Monitor. The 'Single Sign-On' option is selected. The main panel shows the 'New Single Sign-On Server' configuration form. The 'Type' dropdown menu is open, showing options: 'Poll Active Directory Server', 'Fortinet Single-Sign-On Agent' (which is highlighted), and 'RADIUS Single-Sign-On Agent'. Below this, the 'Name' field is empty. The 'Primary FSSO Agent' section contains a 'Server IP/Name' field and a 'Password' field with a toggle for visibility. The 'Collector Agent AD access mode' is set to 'Standard', with 'Advanced' also visible. An 'LDAP Server' dropdown is present. At the bottom of the form, there are three buttons: 'Apply & Refresh' (highlighted in green), 'OK', and 'Cancel'.

2. Create matching User groups. Select **User & Device > User Groups**. Click create New and enter the following data:

- Name- Enter the name of the group. This name will appear in the firewall policy.
- Type- Select **Fortinet Single Sign-On** as type.
- Select the matching User group created on FortiAuthenticator and Click **OK**.

FortiGate VM64 FGVM020000076196 Release Candidate 1

- HC
- REMED
- REMEDATION

Cancel

3. Create a firewall policy to use the IPS enforcement groups just created. Select **Policy & Objects** > **IPv4 Policy**. Click Create **New** and create the policy based on the resource access restrictions to be enforced.

Reports and Logging

You can verify if the syslog messages are reaching the FortiAuthenticator by doing a packet capture on the FortiAuthenticator Interface.

1. Select **System** > **Network** > **Packet Capture** and select the interface which is used to communicate with the IPS and click **Start capture** button. Once packet capture is done stop the capture and download the packets and view it using any tool like wireshark.

- To view identity records from the FortiAuthenticator GUI, Select **Monitor > Sessions**. The list shows the records parsed through syslog.

- You can monitor the FSSO Sessions on FortiGate firewall from CLI or GUI:
Using the FortiGate CLI, type: `diag debug auth fssolist`
The command displays identity records received from FortiAuthenticator.
- Select **Monitor > Firewall user Monitor**. The list shows all the identity records.

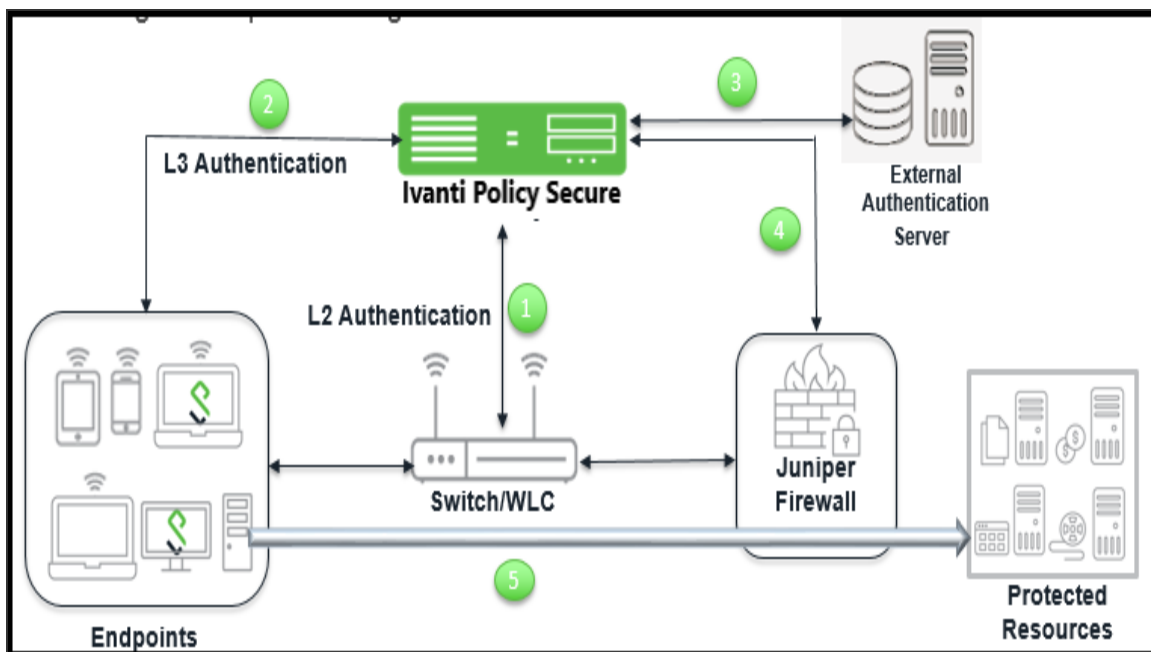

Enforcement using SRX Series Firewall

Overview

IPS delivers a layer 3 network access control solution when deployed with Juniper SRX firewall. The IPS is the Layer 2 or Layer 3 policy decision point that determines which users and endpoints can access protected resources. You can use Juniper Networks SRX firewall to serve as the enforcement point to provide the protection to ensure that network assets are secured. IPS authenticates users, ensures that endpoints meet security policies, and serves resource access policy information to Juniper Networks SRX devices.

Deployment of IPS using SRX Firewall

This section describes the integration of IPS with SRX firewall. The IPS and SRX firewall solution provides functionality for enforcing application level security policies on a per user and role basis. It also delivers granular level access control so that it can be easily managed through IPS.

The authentication process is described below:

1. The endpoint connects to switch to perform the layer 2 authentication with IPS.
2. IPS communicates with authentication server and performs the layer 3 authentication along with host check to ensure that the endpoints meets the corporate policy.
3. The external authentication server such as AD/LDAP confirms the role and sends the entries to IPS.
4. IPS provisions the auth table on SRX firewall with changes in role information if any.
5. The SRX series firewall maps the user to a specific resource access policy and then provides the required access.

Configuring IPS with SRX Firewall

The IPS connects with the SRX device over an SSL connection. To enable the connection between the two devices, you must specify the password and serial number of the SRX firewall. The SRX firewall initiates the connection to IPS. IPS presents its SSL server certificate to the SRX device. Optionally, you can configure the SRX device to verify the certificate and to specify constraints with which IPS must comply.

The SRX device and IPS perform mutual authentication with the proprietary JUEP-MAUTH challenge-response authentication based on the password configured. For security reasons, the password is not included in the message sent to IPS. After the SSL handshake, all further communication between the IPS device and the SRX device occurs over the SSL connection. The SRX device acts as a client and the IPS device as server.

Configuring SRX Infranet Enforcer in IPS

To configure a SRX Firewall Infranet Enforcer in IPS:

1. Select **Endpoint Policy > Infranet Enforcer**.

Infranet Enforcer > Infranet Enforcer Connection

Infranet Enforcer Connection

Connection

Resource

IPsec

Auth Table Mapping

IP Address Pools

A connection policy specifies the connection between the Pulse Policy Secure and Infranet Enforcer.

Note that not all enforcer versions and platforms have an IDP module.

☐ Use IDP Module as Sensor

Save Changes

- Enter the name of the Infranet Enforcer in the **Name** box.
- Enter the password for the SRX enforcer.
- Enter the serial number of the Junos SRX Enforcer. You can view the serial number on the SRX device using the command: `user@host show chassis hardware`
- Ensure that the server certificate for IPS is configured for the interface to which the SRX device is connecting.
- Click **Save Changes**. You must create security policies on the SRX device for traffic enforcement.

Configuring Auth Table Mapping Policies

An auth table consists of username, a set of roles, and IP address of the wired adapter, wireless adapter, or virtual adapter of the user device. Using SRX series firewall you can dynamically create auth table entries when a user tries to access the protected resource. An auth table mapping policy specifies which enforcer device can be used for each user role. These policies prevent the IPS from creating unnecessary auth table entries on all connected enforcer devices.

IPS's default configuration includes only one default auth table mapping policy. When the default auth table mapping policy is enabled, IPS pushes one auth table entry for each authenticated user to all SRX firewalls configured as Infranet Enforcers in IPS.

When you provision the authentication table from IPS to the firewall, ensure that the Profiler is configured with the Profiler Name and upload the FPDB, or do not configure the Profiler. If the Profiler is configured without uploading the FPDB, then the authentication table is not sent from IPS to Firewall.

To configure auth table mapping policies:

1. Select **Endpoint Policy > Infranet Enforcer > Auth Table Mapping**.
2. Select the default auth table mapping policy called **Default Policy** and click **Delete**.

On the New Policy page, do the following:

1. For Name, enter a name to label this auth table mapping policy.
2. (Optional) For Description, enter a description.
3. In the Enforcer section, specify the Infranet Enforcer device(s) to which you want to apply this auth table mapping policy.

4. In the Roles section, specify:
 - Policy applies to ALL roles-To apply this auth table mapping policy to all users.
 - Policy applies to SELECTED roles-To apply this auth table mapping policy only to users who are mapped to roles in the Selected roles list. Be sure to add roles to this list from the Available roles list.
 - Policy applies to all roles OTHER THAN those selected below-To apply this auth table mapping policy to all users except for those who map to the roles in the Selected roles list. Be sure to add roles to this list from the Available roles list.
5. In the Action section, specify auth table mapping rules for the specified Infranet Enforcer device:
 - Always Provision Auth Table-To automatically provision auth table entries for chosen roles on the specified Infranet Enforcer.
 - Provision Auth Table as Needed-To provision auth table entries only when a user with a chosen role attempts to access a resource behind the specified Infranet Enforcer.
 - Never Provision Auth Table-To prevent chosen roles from accessing resources behind the specified Infranet Enforcer.
 - Make sure you delete the Default Policy if you configure any of your own auth table mapping policies. IPS includes this default auth table mapping policy that allows all source IP endpoints to use all Infranet Enforcer devices.
6. If you created a vsys on a ScreenOS Enforcer, enter the ID of the vsys in the vsys text box. To view the enforcers or vsys that are associated with each policy, select Infranet Enforcer > Auth Table Mapping.
7. Click **Save Changes**.

For more information on dynamic authentication table, see [Configuring Dynamic Auth Table Policies](#)

Configuring Resource Access Policy

A resource access policy specifies which users are allowed or denied access to a set of protected resources. You can specify which users you want to allow or deny by choosing the roles for each resource access policy.

To configure Infranet Enforcer resource access policies:

1. Select **Endpoint Policy > Infranet Enforcer > Resource Access Policy** and click **New Policy**.

On the New Policy page do the following:

2. For Name, enter a name to label this Infranet Enforcer resource access policy.
3. (Optional) For Description, enter a description.

For **Resources**, specify the protocol, IP address, network mask, and port of each resource (or range of addresses) for which this Infranet Enforcer resource access policy applies, one per line. Do not insert any spaces in your entries, or the policy may not be applied correctly.

You cannot specify a host name in a resource access policy. You can specify only an IP address. You can use TCP, UDP, or ICMP.

4. Under Infranet Enforcer, specify the Infranet Enforcer to which this policy applies by using Add.
5. Specify one of the following in the Roles section:
 - **Policy applies to ALL roles**-To apply this Infranet Enforcer resource access policy to all users.
 - **Policy applies to SELECTED roles**-To apply this Infranet Enforcer resource access policy only to users who are mapped to roles in the Selected roles list. You must add roles to this list from the Available roles list.
 - **Policy applies to all roles other than those selected below**- To apply this Infranet Enforcer resource access policy to all users except those who map to the roles in the Selected roles list. You must add roles to this list from the Available roles list.
6. In the Action section, specify whether you want to use this Infranet Enforcer resource access policy to allow or deny access to the specified resources.

If you select deny, a text box is displayed that allows you to customize a deny message for users.

With ScreenOS Enforcer Release 6.3 r13 or later, you can also select Reject Access. The customized deny message is available with the reject action.

The reject action is designed for clients that hang for a long period while waiting for connection initiations that the firewall is blocking. With the deny action, the Enforcer drops traffic in accordance with the IPS policy, but does not send back reject information. The policy action of "reject" denies the traffic and sends a TCP RST to the traffic originator for TCP traffic, or ICMP unreachable for UDP traffic. In earlier versions of ScreenOS and on the Junos Enforcer, the selection of reject results in a deny action.

To record deny actions in the User Access Log, select the **Infranet Enforcer Deny Messages** check box on the **Log/monitoring > User Access > Settings** page. The log records the user, source IP, destination IP, protocol, and destination port.

1. For ScreenOS Enforcers, in the ScreenOS Options section, use the option buttons to select the policy options that you want to apply to selected roles. Use the Add and Remove buttons to specify antispam, logging, IDP, web filtering, antivirus, and deep inspection.
2. By default, all policy options are enabled. To enforce the policies, you must create corresponding policies on the ScreenOS Enforcer. If IPS is upgraded from a previous version, all ScreenOS options are enabled for the resource access policies that were available prior to the upgrade.
3. If you have created a vsys on a ScreenOS Enforcer, enter the ID of the vsys in the VSYS text box, if applicable. The Infranet Enforcer > Resource Access Policy page displays the Enforcers and/or vsys that are associated with each policy.

Configuring SRX Firewall

IPS can utilize a SRX device as a policy enforcement point to work as a Layer 3 Enforcer. When the SRX is configured to work as an enforcer with IPS, the following takes place:

- IPS provisions resource access policies.
- SRX gets the user's role membership information from authentication table entries that are sent by IPS when the user authenticates with the IPS or when the user tries to access resources through SRX.
- SRX does a policy lookup in resource access policies, which is sent by IPS and accordingly takes allow/deny decisions.

For the SRX to perform a IPS policy lookup, the uac-policy application service needs to be turned on in the SRX firewall rule and the firewall rule's action should be set to permit. The SRX security policies have to be manually configured on SRX.

Configuring SRX as an Enforcer

The SRX enforcer works with the IPS device for Layer 3 connectivity. You can connect with source IP or IPsec. For the initial setup, you must specify the IPS device name, IP address, port number over which the Junos Enforcer and IPS device will connect, the interface, the password (the same password as entered on the IPS device), and, optionally, the CA profile and server certificate subject. Use the Junos CLI to add this information.

You can configure the SRX device in "test only" mode. In test only mode, the SRX device does not enforce IPS policies and allows all traffic to pass. However, all policy decisions are logged. This allows you to set up the devices before actual deployment and determine how the IPS solution works using different configuration options. For example, the IPS device and endpoints can reside on different physical interfaces of the Junos Enforcer or on the same interface.

IPS device policies are role based. Each policy specifies a destination (the resources that are being protected), a set of roles, and an action (allow or deny). To determine the roles for users, an auth table maps source IP addresses to roles. When an endpoint accesses the IPS device, the IPS device populates the Junos Enforcer with an auth table entry mapping the endpoint's IP address to the endpoint's set of roles. When evaluating a flow, the source IP address of the initial packet is used to look up the roles. Then the first policy that matches both the destination (resource) and the roles is used to determine whether to permit or deny the flow.

To use IPsec with the SRX device, you must enable IKE services for the gateway. If you have multiple IPsec tunnels with multiple gateways, the hostname for each gateway must be unique.

SRX Series communication to IPS is not supported on an interface that is in a routing instance or VRF instance.

To configure the Junos Enforcer:

1. Set up the trusted interface. The trusted interface connects to the protected resource. The untrusted interface connects to IPS.
2. Ensure that the DHCP server is disabled or enabled as required for the deployment.
3. Create a IPS configuration on the Junos security device, and provide the network information required for connecting using the CLI. This information includes IPS host name, the IP address, and the interface to which the device will connect. The default port for communication with IPS is 11123, you cannot change the port. You must also specify a password, that matches the password configured on IPS.

4. For complete CLI instructions and syntax, see the Junos Software CLI Reference.
 - Specify IPS hostname:
user@host# set services unified-access-control infranet-controller hostname
 - Specify IPS IP address:
user@host# set services unified-access-control infranet-controller hostname address ip-address
 - Specify the Junos interface to which IPS should connect:
user@host# set services unified-access-control infranet-controller hostname interface interface-name
 - Specify the password that the SRX Series or J Series device should use to initiate secure communications with IPS:
user@host# set services unified-access-control infranet-controller hostname password password
5. Set the appropriate timeout and interval values, and specify a timeout action. The timeout that you set specifies the elapsed time beyond which the Junos Enforcer attempts to reconnect with IPS if no communication is received. The interval specifies how often IPS sends a heartbeat to the Junos Enforcer.
6. (Optional) Verify that the certificate of the CA that signed IPS's server certificate is loaded in the Junos Enforcer and that the path to the certificate is specified.

Although certificate verification is optional, there are three different certificate options on the Junos Enforcer that will produce different results.

- If certificate-verification is set to required, it is required that the device verify any IPS server certificate. If any IPS ca-profile is not configured, the commit check fails.
 - If certificate-verification is set to warning (the default), and IPS ca-profile is not configured, the commit check displays a warning about the security risk with a similar warning in the syslog.
 - If certificate-verification is set to optional, there is no warning.
7. Verify routing from IPS to the untrusted interface.

8. Ensure that both the Junos Enforcer and IPS are set to the correct time. If possible, use a Network Time Protocol (NTP) Server to set the date and time of both appliances.

When you finish configuring IPS instance, the Junos Enforcer can initiate the connection with IPS. The Junos Enforcer optionally validates IPS server certificate if so configured. The device sends the serial number to authenticate with IPS.

For the Junos Enforcer to establish communication, you must configure the Junos Enforcer on IPS.

Configuring Additional TLS Settings

The user can change different SSL/TLS versions and different encryptions in the Outbound SSL Settings.

To change the SSL/TLS versions:

1. Select **Configuration > Security > Outbound SSL Settings** page.
2. Under Outbound Settings, select **TLS 1.2** for maximum security.

3. Under Allowed Encryption Strength, select Maximum Security (High Ciphers) for maximum security.

Configuration > Security > Outbound SSL Options

☒ Maximize Security (High Ciphers)
☐ Maximize Compatibility (Medium Ciphers)
☐ Custom SSL Cipher Selection

Enforcement using EX Series Ethernet Switches

Overview

You can use the EX Series switch as an Infranet Enforcer with IPS. With this solution, IPS is the policy decision point, while the switch is the policy enforcement point. In prior releases, Layer 3 firewalls were the only option for policy enforcement points. This scenario allows enforcement with 802.1X deployments.

To employ the switch as an Infranet Enforcer, you configure a connection between the EX Series switch and the IPS, establish communication, set up 802.1X, configure IPS parameters for admission to the network, and configure resource access policies.

Upon successful configuration, the following occurs:

- The EX Series switch sends a connection request to IPS.
- The EX Series switch shares its RADIUS configuration with IPS from the CLI configuration on the switch.
- IPS creates the RADIUS client for the EX Series switch using the information provided.
- When a user successfully authenticates, IPS provides an auth table entry to the connected EX Series switch. The auth table includes the MAC address of the user, the assigned roles and the port index.
- IPS must receive the attributes Calling Station ID and Network Access Server (NAS) Port from the switch to successfully make the connection.

Configuring EX switch with IPS

The EX Series switch serves as a policy enforcement point. IPS sends auth table entries and resource access policies when an endpoint successfully completes 802.1X authentication or MAC authentication (unmanaged devices). Access for any endpoint is governed by the resource access policies that you configure on IPS. Because resource access policies are employed, firewall filters are not required for the EX Series switch configuration.

Configuring EX switch as an Infranet Enforcer

The EX-series switches will permit or deny network access based on policies developed and distributed by IPS, including those policies based on user authentication status, endpoint posture compliance, user/device role and other policies. The EX-series switches provide standards-based 802.1X port-level access control.

To configure a Juniper EX switch as an Infranet Enforcer in IPS:

1. Select **Endpoint Policy > Infranet Enforcer**.

The screenshot shows the 'Infranet Enforcer > Infranet Enforcer Connection' page. At the top, there's a breadcrumb 'Infranet Enforcer > Infranet Enforcer Connection' and a title 'Infranet Enforcer Connection'. Below the title is a tabbed interface with tabs: 'Connection' (active), 'Resource', 'IPsec', 'Auth Table Mapping', and 'IP Address Pools'. A green callout bubble points to the 'Connection' tab. Below the tabs, a descriptive text states: 'A connection policy specifies the connection between the Pulse Policy Secure and Infranet Enforcer.' Underneath this text are three buttons: 'New Enforcer...', 'Duplicate...', and 'Delete...'. Below the buttons is a pagination control showing '10 records per page' and a search bar labeled 'Search:'. At the bottom is a table with the following columns: 'Enforcer', 'Serial Numbers', 'Location Group', 'Platform', 'Version', 'FIPS', and 'IP Address'. The table currently contains no data rows.

Enforcer	Serial Numbers	Location Group	Platform	Version	FIPS	IP Address
----------	----------------	----------------	----------	---------	------	------------

- Click **New Infranet Enforcer** and select **Junos EX** in the **Platform** drop down.

Infranet Enforcer > Connection > New Infranet Enforcer

New Infranet Enforcer

♥ Infranet Enforcer

Platform: JUNOS EX Platform of this Infranet Enforcer.

* Name: Label to reference this Infranet Enforcer.

* Password: Connection password.

* Serial number(s): One per line.

* Location Group: - No 802.1X - To manage groups, see the [Location Group](#)

[Save Changes](#)

* indicates required field

- Enter the name of the EX Series switch in the Name box.
- Enter the password for the **EX Series switch**. This password is a shared secret that administrators of both the switch and IPS can use for connectivity between the two devices.
- Enter the serial number of the EX Series switch.
- Select the location group.
- Click **Save Changes**.

On the EX Series switch, you use the CLI to configure the connection with IPS.

Configuring an Authentication Table

The EX Series switch receives and maintains auth tables for valid user sessions with IPS. An auth tables consist of a unique identification number, the MAC address of the endpoint that initiated the session, and a list of roles that the user has been assigned.

Auth tables are sent from IPS to the EX Series switch when a user is authenticated on the network.

Always Provision and Never Provision Auth table mapping policies are supported for the EX Series switch.

For complete configuration information, see [Configuring Auth Table Mapping Policies](#).

Configuring Resource Access Policy

Using resource access policies with an EX Series switch you can configure authorization for protected resources. If you have configured the EX Series switch as an Infranet Enforcer, select the switch in the resource access policy.

A resource is a single entry in the resource field of the resource access policy. This could be a MAC address, or it could be a combination of IP address ranges, ports, and protocol. A filter term is the access/deny detail for a single resource. The number of terms you can configure per firewall filter will vary, depending on which EX Series switch you are configuring. The below table shows the number of terms allowed per firewall filter for different EX Series switches.

EX Switch	Number of Terms Allowed
EX2200 switch	512
EX3200 and 4200 switches	7,042
EX4500 switch	1,536
EX8200 switch	32,768
EX3300 switch	1,436
EX6200 switch	1,400

If you create resource access policies with the number of resources greater than the maximum number of filter terms allowed, the filter is not installed, and 802.1X authentication fails.

For complete information on configuring resource access policy, see [Configuring Resource Access Policy](#).

Enforcement using Screen OS Firewall

Overview

IPS delivers a layer 3 network access control solution when deployed with Screen OS firewall device. The IPS is the policy decision point that determines which users and endpoints can access protected resources. You can use Screen OS firewalls to serve as the enforcement point to provide the ultimate protection to ensure that network assets are secured.

Deployment of IPS using ScreenOS Firewall

This section describes the integration of IPS with ScreenOS firewall. The IPS and Screen OS firewall solution provides functionality for enforcing security policies on a per user and role basis. It also delivers granular level access control so that it can be easily managed through IPS.

The authentication process is described below:

1. The endpoint connects to switch to perform the layer 2 authentication with IPS.
2. IPS communicates with authentication server and performs the layer 3 authentication along with host check to ensure that the endpoints meets the corporate policy.
3. The external authentication server such as AD/LDAP confirms the role and sends the entries to IPS.
4. IPS provisions the auth table on ScreenOS firewall with changes in role information if any.
5. The ScreenOS firewall maps the user to a specific resource access policy and then provides the required access.

Configuring IPS with ScreenOS Firewall

The ScreenOS Enforcer connects to IPS over an SSH connection that uses the NetScreen Address Change Notification (NACN) protocol. IPS uses the NACN password and serial number for a connection from the ScreenOS Enforcer. When the ScreenOS Enforcer first turns on, it sends an NACN message containing the NACN password and serial number to IPS. IPS uses the serial number to determine which ScreenOS Enforcer is attempting to connect, and IPS uses the NACN password to authenticate the ScreenOS Enforcer. IPS then begins communicating with the ScreenOS Enforcer using SSH.

Configuring ScreenOS Infranet Enforcer in IPS

To configure a SRX Firewall Infranet Enforcer in IPS:

1. Select **Endpoint Policy > Infranet Enforcer**.

Infranet Enforcer > Infranet Enforcer Connection

Infranet Enforcer Connection

Connection

Resource

IPsec

Auth Table Mapping

IP Address Pools

A connection policy specifies the connection between the Pulse Policy Secure and Infranet Enforcer.

10 records per page

Search:

	Enforcer	Serial Numbers	Location Group	Platform	Version	FIPS	IP Address

2. Click **New Infranet Enforcer** and select ScreenOS Firewall in the **Platform** drop down.

Infranet Enforcer > Connection > New Infranet Enforcer

New Infranet Enforcer

▼ Infranet Enforcer

Platform: Platform of this Infranet Enforcer.

* Name: Label to reference this Infranet Enforcer.

* NACN password: NetScreen Address Change Notification password.

* Admin username:

* Admin password:

* Serial number(s): One per line.

Location Group: To manage groups, see the [Location Group](#)

▼ Coordinated Threat Control

Note that not all enforcer versions and platforms have an IDP module.

☐ Use IDP Module as Sensor

[Save Changes](#)

* indicates required field

3. Enter an NACN password for this Infranet Enforcer in the NACN password box. You must enter this same NACN password when configuring the Infranet Enforcer.
4. In the appropriate boxes, enter the administrator name and password for signing into the Infranet Enforcer
5. Enter the name of the Infranet Enforcer in the **Name** box.
6. Enter the password for the ScreenOS enforcer.
7. Enter the serial number of the ScreenOS Enforcer. You can view the serial number on the ScreenOS device using the command: **get system**

8. Select **No 802.1X** from the Location Group list if you are not using an Infranet Enforcer as an 802.1X RADIUS client.
9. Ensure that the server certificate for IPS is configured for the interface to which the SRX device is connecting.
10. Click **Save Changes**.

When you finish configuring the Infranet Enforcer, the Infranet Enforcer attempts to connect to IPS. If the connection is successful, a green dot is displayed next to the Infranet Enforcer icon. Under Enforcer Status select **System > Status > Overview**. The Infranet Enforcer IP address is also displayed in **Endpoint Policy > Infranet Enforcer > Connection**.

Configuring Auth Table Mapping Policies

An auth table consists of username, a set of roles, and IP address of the wired adapter, wireless adapter, or virtual adapter of the user device. Using SRX series firewall you can dynamically create auth table entries when a user tries to access the protected resource. An auth table mapping policy specifies which enforcer device can be used for each user role. These policies prevent the IPS from creating unnecessary auth table entries on all connected enforcer devices.

For complete configuration information, see [Configuring Auth Table Mapping Policies](#)

Configuring Resource Access Policy

A resource access policy specifies which users are allowed or denied access to a set of protected resources. You can specify which users you want to allow or deny by choosing the roles for each firewall enforcer access policy.

For complete configuration procedure, see [Configuring Resource Access Policy](#)

Configuring ScreenOS Firewall

IPS can utilize a ScreenOS device as a policy enforcement point to work as a Layer 3 Enforcer. When the ScreenOS device is configured to work as an enforcer with IPS, the following takes place:

- IPS provisions resource access policies.
- Screen OS device gets the user's role membership information from authentication table entries that are sent by IPS when the user authenticates with the IPS or when the user tries to access resources through ScreenOS.
- ScreenOS device does a policy lookup in resource access policies, which is sent by IPS and accordingly takes allow/deny decisions.

Configuring ScreenOS as an Enforcer

You can configure basic Infranet auth Enforcer policies that specify a source zone and a destination zone on the IPS Series device and then push the policies to the ScreenOS Enforcer to add additional policy details, or you can use the ScreenOS Enforcer to configure the policies with the CLI or Web UI. We recommend that you use the IPS Series device to set up the policies for source IP enforcement on the Infranet Enforcer.

Before setting a policy, you must create address book entries for the destination and source addresses unless you use address book entries that already exist, such as Any.

The following example, sets an Infranet auth policy and adds it to the top of the list of policies. The policy allows all traffic of any type from any host to another host. The policy allows traffic according to the Infranet Enforcer resource access policies that you configure on the IPS Series device.

```
set policy top from untrust to trust any permit Infranet-auth
```

The following example sets two address book entries and a policy between them for anyone in the 10.64.0.0/16 range can reach the 10.65.0.0/16 range.

```
set address Trust "10.64 Range" 10.64.0.0 255.255.0.0
set address Untrust "10.65 Range" 10.65.0.0 255.255.0.0
set policy from trust to untrust "10.64 Range" "10.65 Range" any
permit Infranet-auth
```

You can use Route mode or Transparent mode to configure a Juniper Networks ScreenOS Enforcer. By default, the ScreenOS Enforcer operates in Route mode. For more information on ScreenOS, see the *ScreenOS Reference Guide*.

Configuring the ScreenOS in Route Mode

The IPS can reside on trust/untrust interface side of the Infranet Enforcer. If IPS resides on the trust interface side, and users come in through the untrust interface, the administrator must configure a policy (untrust to trust) on the Infranet Enforcer that allows traffic to pass between IPS and Ivanti Secure Access Client. By default, Infranet Enforcer traffic from the untrust interface to the trust interface is denied.

The following procedure describes the setup with IPS on the untrust interface side (same side as users).

To configure an Infranet Enforcer in Route mode:

1. Set up the trust interface. The trust interface connects to the protected resource. The untrust interface connects to IPS. Set the following interface (ethernet1/1) settings:
 - Set routing
 - Enable management of the following services:
 - SSL
 - SSH
 - IP (options)
2. Ensure that the DHCP server is disabled or enabled, as appropriate for the deployment.
3. Import the certificate of the CA that signed IPS's server certificate into the Infranet Enforcer.

4. If you set up an NSRP cluster before you import the CA certificate into the Infranet Enforcer, the CA certificate is automatically synchronized to all Infranet Enforcers in the cluster. However, if you set up the NSRP cluster after you import the CA certificate, you must manually synchronize the certificate to the other Infranet Enforcers in the cluster by typing the following CLI command:

```
exec nsrp sync pki
```

You cannot load the self-signed SSL certificate into the Juniper security device.

The certificate of the CA that signed IPS's certificate must be imported on the Infranet Enforcer because the Infranet Enforcer must be able to trust IPS during an SSL session. When a user signs into a server by means of SSL, the server displays a dialog box in which the user can manually accept the certificate that is associated with that server. For the Infranet Enforcer to skip that manual step and automatically accept IPS's certificate, the Infranet Enforcer must have the certificate of the CA that signed IPS's certificate.

5. Create an instance of IPS on the Juniper security device.
6. Enable SSH.
7. Verify routing from IPS to the untrust interface.
8. Ensure that both the Infranet Enforcer and IPS have the correct time. If possible, use a Network Time Protocol (NTP) server to set the date and time of both appliances.

Creating a Route based interface with ScreenOS

When an interface is in route mode, the security device routes traffic between different zones without performing source NAT.

To create a IPS instance on ScreenOS, you must configure the following items:

- IP address or hostname of IPS
- Password to use when the Infranet Enforcer uses NACN to contact IPS
- Source interface
- CA index number (ca-idx)

You can set these items using the Web UI or the CLI.

In the following procedure, you first set interface management options and disable the DHCP server option. Then you enable SSHv2 and configure an IPS server named controller1. Next, you set the host IP address, which is the IP address of the server, to 10.64.12.1. The NACN password is 8!JsP37cK9a*_HiEwe. The NACN password must match the NACN password that you entered for IPS server. The source interface is the interface that the Infranet Enforcer uses to communicate with IPS, and the CA index number is 001.

For this example, the source interface is ethernet 1/1. For a descriptive list of CA index numbers by typing the following command at the ScreenOS CLI:

```
get ssl ca-list
```

To change SSH versions, delete SSH settings by typing the following CLI command:

```
delete ssh device all
```

When you use the Web UI, you do not need to fill in the Full Subject Name of IPS Cert field. If you do fill it in, be sure to enter the entire certificate subject. For example:

```
CN=ic1.sample.net,CN=14087306185,CN=06990218,OU=Software,O=Comp,S=CA,C=US
```

To create the instance using the Web UI:

1. Select **Network > Interfaces > Edit > Services** from the left navigation bar to set management options.
2. Select **Network > DHCP > Edit** to disable the DHCP server for both interfaces (Trust and Untrust).
3. Select and load the CA if you have not already done so.
4. Select **Objects > Certificates**.
5. Click **Browse** to find and select the certificate. Then click **Load**.
6. Select **CA** from the show list.
7. Click **Server Settings** and make sure **Check Method** is set correctly for the certificate you are using.
8. Click **OK**.
9. Create IPS instance.

10. Select **Configuration > Infranet Auth > Controllers (List) > New**.
11. Type **controller1** in IPS instance box.
12. Type IP/domain name: **10.64.12.1** in the IP/Domain Name box.
13. For the NACN Parameters, select ethernet1/1 from the Source Interface list.
14. Type **8!JsP37cK9a*_HiEwe** in the Password box.
15. Select the CA from the **Selected CA** list.
16. Enable SSH version 2.
17. Select **Configuration > Admin > Management > Enable SSH (v2)**.

To create the instance using the CLI:

Type the following commands

```
set interface ethernet1/1 manage ssl
set interface ethernet1/1 manage ssh
set interface ethernet1/1 manage ip
set interface ethernet2/1manage ping
set interface ethernet2/1 dhcp server disable
set interface ethernet1/1 dhcp server disable
delete ssh device all
set ssh version v2
set ssh enable
set infranet controller name controller1 host-name 10.64.12.1
set infranet controller name controller1 password 8!JsP37cK9a*_HiEwe
set infranet controller name controller1 src-interface ethernet1/1
set infranet controller name controller1 ca-idx 001
save
```

Configuring the ScreenOS in Transparent Mode

The ScreenOS device is usually installed between a core router and an access distribution device in a transparent mode. The services are enabled at the zone level, and VLAN1 is used for management.

Transparent mode permits you to implement the following functionality:

- The device can act as a Layer 2 forwarding device, such as a bridge.
- You can control traffic flow between Layer 2 security zones by defining policies.

To configure a ScreenOS Enforcer in Transparent mode:

1. Set up Transparent mode using the predefined security zones, v1-trust and v1-untrust.
2. Assign interfaces to v1-trust and v1-untrust.
3. Configure the IP address for a source interface to establish connectivity with IPS. You can use V1-trust, V1-untrust, or V1-dmz.
4. Configure the broadcast mechanism to flooding (default) or ARP/traceroute. ARP/trace-route is more secure than broadcast.
5. Enable management of the following services for VLAN1:
 - SSL
 - SSH
 - Web (optional)
6. Set up the Juniper Networks security device zones. The protected resources can be in either zone (v1-trust or v1-untrust) as long as the protected resources are in a zone different from the endpoints.
IPS can also reside in either zone. If IPS resides in a zone different from the endpoints, configure a policy that allows traffic to the endpoints through the ScreenOS Enforcer.
7. Import the certificate of the CA that signed IPS's server certificate into the ScreenOS Enforcer. Do not import IPS SSL certificate into the Juniper Networks security device.
8. Create an instance of IPS on the ScreenOS Enforcer.
9. Enable SSH.
10. Verify routing from IPS to the V1-untrust zone.
To use IPsec enforcement with a ScreenOS Enforcer in Transparent mode, you might need to configure a source interface policy on IPS.
11. Ensure that both the Infranet Enforcer and IPS have the correct time. If possible, use a Network Time Protocol (NTP) server to set the date and time of both appliances.

Creating a Transparent Mode instance on the ScreenOS

To create a IPS instance in transparent mode, use the CLI to perform the following actions:

- Assign all interfaces to Layer 2 zones.
- Assign an IP address to vlan1 and set the route command.
- Set interface management options.
- Configure a IPS instance named controller1.
- Set the host IP address, which is the IP address of IPS, to 10.64.12.1.
- Enter the NACN password. The NACN password is 8!JsP37cK9a*_HiEwe. The NACN password must match the NACN password that you entered for IPS.
- The source interface, vlan1, is the interface that the Infranet Enforcer uses to communicate with IPS. The CA index number is 001. For a descriptive list of CA index numbers type the following CLI command: `get ssl ca-list`

You can use the following sample configuration to create the instance using the CLI.

For the firewall to operate in Transparent (Layer 2) mode, all interfaces must be in a Layer 2 zone, such as v1-trust or in the null zone. Interfaces cannot remain in a Layer 3 zone.

```
set interface eth1 zone v1-trust
set interface eth2 zone v1-untrust
set interface vlan1 ip 10.64.12.x
set interface vlan1 route
set interface vlan1 ip manageable
unset interface vlan1 manage ping
unset interface vlan1 manage telnet
unset interface vlan1 manage snmp
unset interface vlan1 manage web
set infranet controller name controller1 host-name 10.64.12.1
set infranet controller name controller1 password 8!JsP37cK9a*_HiEwe
set infranet controller name controller1 src-interface vlan1
set infranet controller name controller1 ca-idx 0001
```

Verifying the IPS Configuration on ScreenOS Enforcer

You can view the configuration of a IPS instance through the Web UI and the CLI. You can view the following information:

- Name of IPS instance
- IP address or domain name of IPS
- Port number (Default 11122)
- Timeout (60 seconds by default)
- Source interface

The Web UI also allows you to view the NACN password.

Web UI

To view configuration information on the Web UI select the following:

1. **Configuration > Infranet Auth > Controllers** from the left navigation bar.
2. **Configuration > Infranet Auth > General Settings** from the left navigation bar.

CLI

To view configuration information at the CLI, type the following command:

```
get infranet controller name controller1
```

Appendix

Infranet Enforcer Policies Overview

After you set up user roles, authentication servers, realms and sign-in policies, you deploy the Infranet Enforcer in front of servers and resources that you want to protect. You control access through a number of different security policies that you configure on Ivanti Policy Secure.

All policy options are supported on the ScreenOS Enforcer.

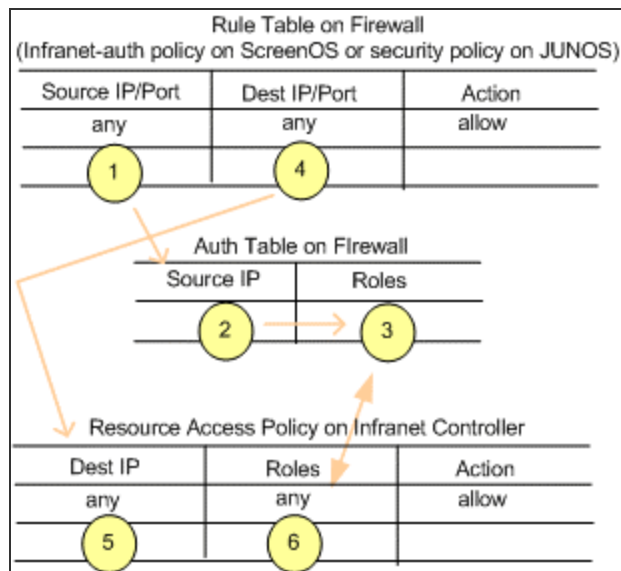

Resource access policy-Specifies which users are allowed or denied access to a set of protected resources. You specify which users you want to allow or deny by choosing roles for each resource access policy.

Source IP policy-This is an infranet auth policy the on ScreenOS Enforcer or a security policy on the Junos Enforcer that contains a source and destination that permits the Infranet Enforcer to route clear text traffic between source and destination zones. You can set up a source IP policy on Ivanti Policy Secure and push the policy to the Infranet Enforcer, or you can set up the policy using ScreenOS Web UI or the command line.

Auth table mapping policy-Specifies which Infranet Enforcer device an endpoint must use to access resources when the endpoint is using source IP enforcement. If you are using either a ScreenOS Enforcer with Release 6.1 or later or the Junos Enforcer, you do not need to configure auth table mapping policies. Instead, you can use dynamic auth table provisioning.

i You can use a username with spaces, a username with quotation marks, a username with UTF-8 characters, or a username with a backslash (\). Each of these conventions is accepted by the firewall with a valid corresponding auth table entry.

The following figure demonstrates how policies on the Infranet Enforcer and Ivanti Policy Secure interact when a user has an auth table entry on the Infranet Enforcer.

The Infranet Enforcer detects a flow to a specific resource and compares the source IP of the packet with IP addresses in the auth tables. The IP address is associated with a set of roles in the auth table. The destination IP of the packet is matched with the destination IP of a resource access policy to which a set of roles has been assigned. The Infranet Enforcer parses the roles in the resource access policy to determine whether or not the role can access the resource.

Understanding Infranet Enforcer Source IP Security Policies

This topic provides an overview of Infranet Enforcer source IP security policies.

Source IP Security Policy Overview

Source IP enforcement permits users to access resources that are protected by the Infranet Enforcer. IPsec provides an encrypted tunnel for bidirectional traffic, while source IP enforcement allows unencrypted (clear text) traffic between endpoints and the Infranet Enforcer. You can use source IP enforcement alone on the Infranet Enforcer to protect resources alone, or with IPsec on the ScreenOS Enforcer.

To use source IP enforcement, you configure Ivanti Policy Secure policies. On a ScreenOS Enforcer, an Ivanti Policy Secure policy is an infranet auth policy (a policy that includes an infranet-auth statement). On a Junos Enforcer, an Ivanti Policy Secure policy is a security policy (a security policy that includes an application-services Ivanti Policy Secure-policy statement, and may or may not also include a match source-identity statement for user-role firewall functionality).

Ivanti Policy Secure policies control which zones use Infranet Enforcer resource access policies to allow or deny traffic. By default, traffic is denied through the Infranet Enforcer. With Ivanti Policy Secure policies, you control the traffic that is permitted to pass.

When you first set up the Infranet Enforcer and Policy Secure, you bind zones to interfaces. Ivanti Policy Secure policies control the traffic flow between zones. For example, you can configure an Ivanti Policy Secure policy on the ScreenOS Enforcer to enforce traffic from the Untrust zone to the Trust zone. Then, you configure resource access policies and specify resources that are within the Trust zone. The roles that you assign to the resource access policy are permitted to access the specified resources.

Source IP enforcement does not work if there is a NAT device between the endpoint and Ivanti Policy Secure.

In a case where the endpoint is behind a NAT device and Ivanti Policy Secure and the Infranet Enforcer are both on the other side of the NAT device, only one configuration is supported. Source IP enforcement works only with agentless access, and only if it is "one-to-one" NAT, since Ivanti Policy Secure and the Infranet Enforcer both see the external (translated) address, and there will be only one user session per IP address.

Source IP enforcement with agentless access might appear to work, but does not operate properly, if an endpoint is behind a NAT device performing is "many-to-one" NAT. The first user that authenticates from behind the NAT external IP address will get access, but only as long as they are the only authenticated user. If a second user authenticates from behind the same external (translated) IP address, the previous user's session is terminated. The web browser shows that their session was terminated, the same as if an Ivanti Policy Secure administrator deleted their session from the active user table.

If the endpoint is behind a NAT device, Source IP enforcement with Ivanti Secure Access Client does not work at all, regardless of the type of NAT. The agent reports the internal IP address of the endpoint, but the IC will see the external IP of the endpoint. The user can authenticate, and the active user table displays X.X.X.X-Y.Y.Y.Y, where X.X.X.X is the IP address reported by the agent and Y.Y.Y.Y is the IP address detected by the IC. However, no auth table entry will be provisioned to the firewall, since Ivanti Policy Secure detects that the endpoint is behind a NAT.

To provide access for Ivanti Secure Access Client behind a NAT device, you must use the IPsec policy feature. The IPsec enforcement section provides instructions on how to accommodate users in this use case.

ScreenOS Infranet Enforcer Configuration Summary

You can configure Source IP security policies in either of the following ways:

- You can configure basic Source IP policies (source and destination zone) on Ivanti Policy Secure and then push the policies to the ScreenOS Enforcer to add additional policy details. (Recommended)
- You can configure the policies directly on the ScreenOS Enforcer (using the ScreenOS Web UI or CLI).

- To use ScreenOS global policies as infranet auth policies, you must configure them directly on the ScreenOS Enforcer. ScreenOS global policies do not include source and destination zones, and policies pushed from Ivanti Policy Secure must include source and destination zones, so the infranet auth policy pushed by Ivanti Policy Secure is not useful when configuring ScreenOS global policies.
- On ScreenOS, you create a policy using address book entries for the destination and source addresses, as well as policy wildcards, such as Any.

The following example sets an infranet auth policy and adds it to the top of the list of policies controlling traffic from the Untrust zone to the Trust zone. The policy applies to all traffic of any type from any host to another host. The policy allows traffic according to the Infranet Enforcer resource access policies that you configure on Ivanti Policy Secure.

```
set policy top from untrust to trust any permit infranet-auth
```

The following example sets two address book entries and a policy for anyone in the 10.64.0.0/16 range to reach the 10.65.0.0/16 range, subject to resource access policies.

```
set address Trust "10.64 Range" 10.64.0.0 255.255.0.0
set address Untrust "10.65 Range" 10.65.0.0 255.255.0.0
set policy from trust to untrust "10.64 Range" "10.65 Range" any
permit infranet-auth
```

Junos Infranet Enforcer Configuration Summary

On the Junos Enforcer, security policies enforce rules for the transit traffic. From the perspective of security policies, traffic enters one security zone and exits another. This combination of a from-zone and a to-zone is called a context on the Junos Enforcer.

A security zone is a logical group of interfaces with identical security requirements. Each security zone contains an address book. Before you can set up policies between two zones, you must define the addresses for each of the zone's address books. A zone's address book must contain entries for the addressable networks and end hosts belonging to the zone.

Each security policy that you create must contain at a minimum match criteria and an action. You can specify additional policy options as required.

You can create security policies on the Junos Enforcer from the Junos Web interface, or from the CLI.

The following example sets an Ivanti Policy Secure-policy security policy controlling traffic from the Untrust zone to the Trust zone. The policy applies to all traffic of any type from any host to another host. The policy allows traffic according to the Infranet Enforcer resource access policies that you configure on Ivanti Policy Secure.

```
set security policies from-zone Untrust to-zone Trust policy ENFORCE_  
ALL match source-address any  
set security policies from-zone Untrust to-zone Trust policy ENFORCE_  
ALL match destination-address any  
set security policies from-zone Untrust to-zone Trust policy ENFORCE_  
ALL match application any  
set security policies from-zone Untrust to-zone Trust policy ENFORCE_  
ALL then permit application-services uac-policy
```

The following example sets two address book entries and a policy for anyone in the 10.64.0.0/16 range to reach the 10.65.0.0/16 range, subject to resource access policies.

```
set security zones security-zone Trust address-book address 10.64_  
Range 10.64.0.0/16  
set security zones security-zone Untrust address-book address 10.65_  
Range 10.65.0.0/16  
set security policies from-zone Trust to-zone Untrust policy ENFORCE_  
ALL match source-address 10.64_Range  
set security policies from-zone Trust to-zone Untrust policy ENFORCE_  
ALL match destination-address 10.65_Range  
set security policies from-zone Trust to-zone Untrust policy ENFORCE_  
ALL match application any  
set security policies from-zone Trust to-zone Untrust policy ENFORCE_  
ALL then permit application-services uac-policy
```

Understanding Infranet Enforcer Auth Tables

The Infranet Enforcer holds auth tables for valid sessions on Ivanti Policy Secure. Auth tables consist of a unique identification number, the source IP address of the endpoint that initiated the session, the username, and a list of roles that the user has been assigned.

When a user with a username containing spaces or quotes authenticates with Ivanti Policy Secure, the device removes spaces and quotes from the username in the authentication table entry that is sent to Infranet Enforcers.

You can allow the Infranet Enforcer to automatically generate auth tables whenever users are authenticated, or you can configure dynamic auth table allocation. With dynamic auth table allocation, auth tables are provisioned only as a response to a valid request from an authenticated user for a resource behind the Infranet Enforcer.

Dynamic auth table allocation is available on all Junos Enforcers, and on ScreenOS Enforcers with Release 6.1 or later.

Understanding Dynamic Auth Table Allocation

You can use the dynamic auth table allocation feature to push auth table entries to the Infranet Enforcer only when a user attempts to access a protected resource. This is more efficient than the Auth Table Mapping Policies option, which requires administrators to provision auth table entries for authenticated users whether they are accessing resources or not. Dynamic auth table allocation reduces auth table entries to only those that are needed, enabling you to deploy smaller firewalls with a larger user population.

When dynamic auth table allocation is used and a user attempts to access a protected resource, the Infranet Enforcer does not yet have an auth table entry for the user, so it sends a drop notification to Ivanti Policy Secure to prompt it to send an auth table entry. Unlike captive portal redirect, which only occurs when the user sends HTTP traffic, drop notifications are triggered by any type of traffic for which the destination is a protected resource.

After the user disconnects, the Infranet Enforcer automatically expires the auth table entry.

On the Junos Enforcer, whenever traffic matches a security policy that includes an application-services uac-policy statement, then the firewall sends a drop notification to Ivanti Policy Secure if there is no auth table entry associated with that traffic. This applies in the captive portal use case, and for all policies that include the application-services uac-policy statement.

However, this behavior changes if user role firewall is configured. When a match source-identity statement is included in any policy within a zone pair (source zone + destination zone), user and role information must be retrieved before policy look-up can proceed. (If all policies in the zone pair are set to match source-identity any, or have no match source-identity state, user and role information is not required and the five standard match criteria are used for policy look-up.) Therefore, for any zone pair in which a security policy is configured that contains a match source-identity statement, the firewall sends a drop notification for all traffic matching that source and destination zone, whether or not the traffic matches the specific security policy containing the match source-identity statement. This can result in an unexpected number of drop notifications if a single zone contains a mix of protected and unprotected resources.

In most deployments, it is recommended that you use dynamic auth table allocation. The benefits of dynamic auth table allocation are based on many factors within the network deployment: the number of Infranet Enforcers, the anticipated number of sessions, and the persistence of user sessions.

The following requirements and limitations apply:

- Dynamic auth table allocation is supported for all deployments with Junos Enforcer and with ScreenOS Enforcers running ScreenOS 6.1 or later.
- Dynamic auth table allocation does not work with HTTP traffic if the captive portal feature is configured to redirect user traffic to an external web server other than Ivanti Policy Secure. Ivanti Policy Secure must be aware of a user login/session before it can provision an auth table entry.
- If you configure dynamic auth table allocation on Ivanti Policy Secure, and the DNS server for the network is behind the Infranet Enforcer, endpoints might occasionally experience DNS time-out issues before resources are provisioned.

One scenario in which static auth tables are more practical is a deployment that forces every endpoint to go through a single Infranet Enforcer for all access. In this case, static auth tables can reduce overall traffic between Ivanti Policy Secure servers and Infranet Enforcers.

For deployments that use static auth table mapping policies (for example, if you are using a ScreenOS Release 6.1 or earlier), we recommend no more than 100 connected Infranet Enforcers. For deployment scenarios with more than 100 Infranet Enforcers, we recommend a deployment strategy using dynamic auth table allocation.

Testing has shown that with 5,000 active sessions, performance is impacted significantly when dynamic auth table allocation is not configured and 100 connected firewalls are deployed.

Performance metrics vary for each Ivanti Policy Secure release.

Configuring Dynamic Auth Table Policies

You can use the dynamic auth table allocation feature to push auth table entries to the Infranet Enforcer only when a user attempts to access a protected resource. This is more efficient than the Auth Table Mapping Policies option, which requires administrators to provision auth table entries for authenticated users whether they are accessing resources or not. Dynamic auth table allocation reduces auth table entries to only those that are needed, enabling you to deploy smaller firewalls with a larger user population.

When dynamic auth table allocation is used and a user attempts to access a protected resource, the Infranet Enforcer does not yet have an auth table entry for the user, so it sends a drop notification to IPS to prompt it to send an auth table entry. Unlike captive portal redirect, which only occurs when the user sends HTTP traffic, drop notifications are triggered by any type of traffic for which the destination is a protected resource.

After the user disconnects, the Infranet Enforcer automatically expires the auth table entry.

On the SRX device, whenever traffic matches a security policy that includes an application-services uac-policy statement, then the firewall sends a drop notification to IPS if there is no auth table entry associated with that traffic. This applies in the captive portal use case, and for all policies that include the application-services uac-policy statement.

However, this behavior changes if user role firewall is configured. When a match source-identity statement is included in any policy within a zone pair (source zone + destination zone), user and role information must be retrieved before policy look-up can proceed. (If all policies in the zone pair are set to match source-identity any, or have no match source-identity state, user and role information is not required and the five standard match criteria are used for policy look-up.) Therefore, for any zone pair in which a security policy is configured that contains a match source-identity statement, the firewall sends a drop notification for all traffic matching that source and destination zone, whether or not the traffic matches the specific security policy containing the match source-identity statement. This can result in an unexpected number of drop notifications if a single zone contains a mix of protected and unprotected resources.

In most deployments, it is recommended that you use dynamic auth table allocation. The benefits of dynamic auth table allocation are based on many factors within the network deployment: the number of Infranet Enforcers, the anticipated number of sessions, and the persistence of user sessions.

The following requirements and limitations apply:

- Dynamic auth table allocation is supported for all deployments with Junos Enforcer and with ScreenOS Enforcers running ScreenOS 6.1 or later.
- Dynamic auth table allocation does not work with HTTP traffic if the captive portal feature is configured to redirect user traffic to an external web server other than IPS. IPS must be aware of a user login/session before it can provision an auth table entry.
- If you configure dynamic auth table allocation on IPS, and the DNS server for the network is behind the Infranet Enforcer, endpoints might occasionally experience DNS time-out issues before resources are provisioned.

One scenario in which static auth tables are more practical is a deployment that forces every endpoint to go through a single Infranet Enforcer for all access. In this case, static auth tables can reduce overall traffic between IPS servers and Infranet Enforcers.

For deployments that use static auth table mapping policies, we recommend not more than 100 connected Infranet Enforcers. For deployment scenarios with more than 100 Infranet Enforcers, we recommend a deployment strategy using dynamic auth table allocation. Testing has shown that with 5,000 active sessions, performance is impacted significantly when dynamic auth table allocation is not configured and 100 connected firewalls are deployed. Performance metrics vary for each IPS release.

To enable dynamic auth table allocation:

1. Select **Infranet Enforcer > Auth Table Mapping** in the admin console. Either delete the Default Policy or specify an Enforcer for which you do not want to configure this feature.
2. Click **Save Changes**.

Binding an Interface to a Security Zone on a Junos Enforcer

Interfaces are the doorways through which traffic enters and exits an Enforcer. Many interfaces share the same security requirements. However, different interfaces can have different security requirements for inbound and outbound data packets. Interfaces with identical security requirements can be grouped together in a single security zone.

A security zone is a collection of network segments that require the regulation of inbound and outbound traffic through policies. Security zones are logical entities to which one or more interfaces are bound. Many types of Enforcers let you define multiple security zones based on network requirements.

You can configure multiple security zones by dividing the network into segments to which you can then apply various security options to satisfy the needs of each segment. At a minimum, you must define two security zones, basically to protect one area of the network from the other. On some security platforms, you can define many security zones, bringing finer granularity to the network security design without deploying multiple security appliances to do so.

From the perspective of security policies, traffic enters one security zone and exits through another security zone. This combination of a "from-zone" and a "to-zone" is defined as a context. Each context contains an ordered list of policies. On the Junos Enforcer, you must define at least two zones to protect one area of the network from another.

You might need to bind the physical interfaces on a Juniper security device to security zones or you might need to change a binding to accommodate your deployment.

Slot numbering varies by platform, and interface numbering varies by module type. For numbering information, see the user guide that accompanied the device for slot and interface numbering information or visit <https://www.ivanti.com/support/product-documentation> to obtain a copy of the user guide specific to your device.

Endpoints must reside in a different security zone from your protected resources. IPS can reside in any security zone. If you place IPS in a different security zone from the one that contains endpoints, you must set a policy allowing traffic from the endpoints to IPS.

Through the policies you define, you can permit traffic between zones to flow in one or both directions. The routes that you define specify the interfaces that traffic from one zone to another must use. Because you can bind multiple interfaces to a zone, the routes you chart are important for directing traffic to the interfaces of your choice.

To view the zones on a Junos Enforcer, type the following command in the CLI:

```
user@host#show security zones
```

To bind the physical interface on the Junos Enforcer, do the following:

- To configure the interface and its IP address for the trust and untrust zones, enter the following statement in Edit mode:

```
user@host# set interfaces ge-0/0/1 unit 0 family inet address  
192.168.0.1/24
```

- To configure the trust zone and to assign the interface to it, enter the following statement in Edit mode:

```
user@host# set security zones security-zone trust interfaces interface
```

- To configure the interface and its IP address for the untrust zone, enter the following statement in Edit mode:

```
user@host# set interfaces ge-0/0/1 unit 0 family inet address  
10.0.0.20/24
```

- To configure the untrust zone and to assign the interface to it, enter the following statement in Edit mode:

```
user@host# set security zones security-zone untrust interfaces  
interface
```

To use IPsec with the Junos Enforcer, you must enable IKE services for the gateway. If you have multiple IPsec tunnels with multiple gateways, the hostname for each gateway must be unique.

Captive Portal

Captive portal enables an endpoint to be redirected to a specified URL when the user attempts to access a protected resource behind an Infranet Enforcer. The default redirection page is the authentication page of IPS.

The Captive Portal workflow is described below:

1. The user attempts to access a protected resource.
2. The generic source IP policy that matches the destination includes a redirect configuration.
3. The enforcer sends a redirect message to the endpoint browser that includes the URL of IPS.
4. The browser opens a session with IPS and the endpoint completes authentication.
5. IPS sends an authentication table information to Enforcer.
6. IPS redirects the browser back to the original resource.
7. The user tries to access the resource and the enforcer allows the user to access the protected resource.

Configuring Captive Portal

You can configure a captive portal directly on the Infranet enforcer using the CLI. You must create a captive-portal application service and then set the traffic that would like to redirect:

- **unauthenticated**-Select this option if your deployment uses source IP only or a combination of source IP and IPsec. The Infranet Enforcer redirects clear-text traffic from unauthenticated users to the currently connected IPS, or to an IP address or domain name that you specify in a redirect URL.
- **all**-Select this option if your deployment uses IPsec only. The Infranet Enforcer redirects all clear-text traffic to the currently connected IPS, or to an IP address or domain name that you specify in a redirect URL.

- The captive portal feature redirects HTTP traffic only. If the user attempts to access a protected resource using HTTPS or another protocol such as SMTP, the Infranet Enforcer does not redirect the user's traffic. When using HTTPS or another application, the user must manually sign into IPS first before attempting to access protected resources.
- If there is an HTTP proxy between the endpoint and the Infranet Enforcer, the Infranet Enforcer might not redirect the HTTP traffic.

Example: Junos SRX CLI

To use captive portal with the Junos Enforcer, Release 10.2 is required.

To enable captive portal. associate an instance of a captive portal with a security zone use the following command format:

```
user@host# set security policies from-zone zone-name to-zone zone-name policy policy-name
```

To create the captive portal use the following command format:

```
user@host# permit application-services uac-policy captive-portal captive-portal-name
```

You can redirect all traffic, or only unauthenticated traffic on the Junos Enforcer using the following command format:

```
# edit services unified-access-control captive-portal policy
redirect-traffic (all | unauthenticated)
```

Example: ScreenOS CLI

To configure a redirect infranet auth policy for deployments that use either source IP only or a combination of source IP and IPsec type the following command:

```
set policy from source-zone to dest-zone src_addr dst_addr any permit
infranet-auth redirect-unauthenticated
```

To configure a redirect infranet auth policy for deployments that use IPsec only type the following command:

```
set policy from source-zone to dest-zone src_addr dst_addr any permit
infranet-auth redirect-all
```

Creating a Redirect Policy on the Junos Enforcer

In a Junos Enforcer security policy, specify the redirect URL in the following format:

```
user@host# set services unified-access-control captive-portal policy
redirect-url url
```

By default, after you configure a captive portal policy, the Junos Enforcer redirects HTTP traffic to the currently connected IPS by using HTTPS. To perform the redirection, the Junos Enforcer uses the IP address or domain name that you specified when you configured IPS instance on the Junos Enforcer.

You specify the redirect URL in a Junos Enforcer security policy using the following hierarchy:

```
user@host# set services unified-access-control captive-portal cap-
policy redirect-url "https://%ic-ip%/?target=%dest-
url%&enforcer=%enforcer-id%&policy=%policy-id%"
```

These are the four available parameters for redirection.

- target
- enforcer
- policy
- dest-ip

Target, enforcer, and policy are required. Dest-ip is optional. For example:

```
redirect-url "https://acmegizmo.juniper.net/?target=%dest-  
url%&enforcer=%enforcer-id%&policy=%policy-id%"
```

If you do not specify the redirect URL, the Junos Enforcer uses the default configuration.

To set a redirect URL for the Junos Enforcer, use escape characters instead of dot (.).

For configuration instructions and examples, see the *Junos OS Initial Configuration Guide for Security Devices*.

Creating a Redirect Policy on the ScreenOS Enforcer

From the ScreenOS CLI

- To specify the redirect URL, enter: `set infranet controller name controller1 url "http://10.64.12.1/?target=%dest-url%"`
- To specify the redirect URL without the `?target=%dest-url%` string, enter: `set infranet controller name controller1 url http://abc.company.com`

Visibility based Firewall Enforcement

Overview

Profiler provides visibility of the endpoints connected to network. On Profiler, Profile groups can be created using an attribute or combination of device attributes.

The profiler discovered and classified devices with matching attributes belong to configured groups. In few customer environments such as manufacturing industries devices should be able to access applications/resources protected by firewall.

In such scenarios, IPS allows Administrator to provision Auth Table Mapping policy and Resource Access policy configured using profile groups for the devices. IPS provisions the device identity information to the firewall and then Administrator can configure firewall policy based on the requirement.

The provisioning of device information to firewall is described below:

1. Profiler configured on IPS discovers devices connected to network.
2. IPS gets the profiled device information, which belongs to one or more groups. IPS then uses this device information to provision Auth Table Mapping to firewall. The Auth Table Mapping policy defines Profile Group based access control to firewall protected devices.
3. Device Identity details (user id: MAC address of the device, IP address and Profile Group Name) are provisioned to firewall.
4. Device tries to access resources protected by firewall. Devices are allowed to access resources behind firewall based on Profile Group.
5. Any change to Profile Group information for a device will be updated in the firewall.

- SRX security policy applies to the role ID and not the role name. Hence, IPS exports Profile group IDs to SRX and not the Profile group names.

- Resource access policy and IoT policy configured based on Profile groups will be exported to firewall along with group information.

Configuring Firewall Provisioning based on Profile Group

To configure firewall provisioning based on Profile group:

1. Admin configures local profiler on IPS to discover devices connected to network. For Profile group configuration, see [Configuring Profiler Groups](#). Auth Table Timeout option is used for dynamic auth table policy provisioning to firewall (Applies only to SRX firewall).

Profiler Configuration > Profile Groups

Switches

 Edit Profile Group

Group Name *

Switches [Devices in this group](#)

Rule

The rules can be written as a 'query' using profiler attributes. Start typing to get autofilling options.
Example: Switches by Cisco can be grouped as: category = "switch*" and manufacturer = "cisco"
A complex rule using inner attributes: (snmp.switch_ip = "10.204.58.77" and manufacturer != "juniper") or (os != "juniper" and ip = "10.204")

category = "Switch*"

☒ Auto-Approval ☐ Manual-Approval ☐ Time-Bound-Approval

☐ Send email notifications whenever a new device enters this group.

Auth Table Timeout

60 Seconds (60 - 86400 seconds)

Auth table idle timeout value is used for Firewall provisioning, when action is configured as "Provision Auth Table As Needed" in Auth table mapping policy.

Purge devices older than:

Never

Device(s) older than selected option would be deleted permanently from database automatically. Automatic Purge will trigger every 24 hours Or it can be manually triggered using "Actions" menu in Device Discovery Report. This is based on the last updated time of the device.

 Save  Delete this group

2. Configure firewall as an Enforcer, select **Endpoint Policy > Infranet Enforcer > Connection** and add the enforcer.
3. Configure Auth Table Mapping Policy based on Profile Group, select **Endpoint Policy > Infranet Enforcer > Auth Table Mapping**. Under Provision Settings, enable **Provision Auth Table based on Profile Groups**.

4. Select the Profile Group to which the policy applies and click Add and then click Save Changes.

- If there are Auth Table Mapping Policies based on Roles as well as Profile Groups and if there is an authenticated session for an endpoint which is also profiled and belongs to group(s), then user roles will be given precedence over profiler groups for firewall provisioning.
- If the user is logged out but profiled information is still available in the Profiler database then endpoint information will not be provisioned to firewall based on profile groups. However, it will be synced with firewall during next reconciliation.
- If there is an authenticated session and if the Auth Table Mapping policy provisioning is changed to groups from roles then the corresponding entry may get deleted from the firewall if there are no other policies applying to the user role(s).

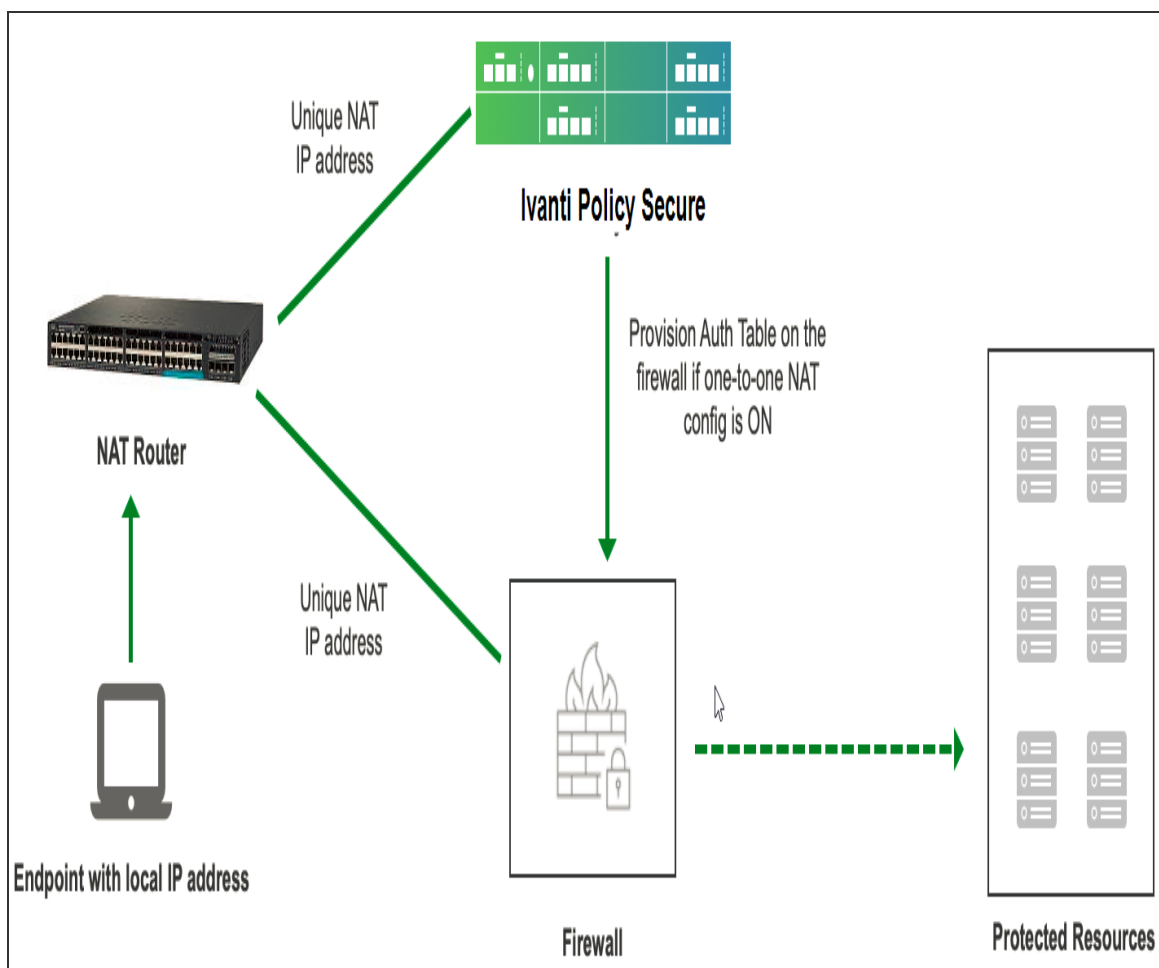

One-to-One Network Address Translation

Overview

One-to-One NAT is the process that maps one internal private IP address to one external public IP address. This helps to protect the private IP addresses from any malicious attack or discovery as the private IP addresses are kept hidden. IPS allows admin to provision auth table entries for endpoints behind one-to-one NAT deployment.

One-to-One NAT Deployment

In this deployment, each end user is having their local address and they are assigned a unique NAT IP address. IPS labels the end user as behind NAT for this type of deployment. The resources are provisioned to firewall only if the Provision Auth table for endpoints behind one-to-one NAT deployment option is enabled on IPS.

The authentication process is described below:

1. User behind one-to-one NAT logs in and the corresponding user role is assigned.
2. A matching auth table mapping policy is detected. If configuration for **Provision Auth table for one-to-one NAT Deployment** option is enabled in this policy, then authentication table for external public IP address for the user is pushed on the firewall.
3. User logs out and all the external public IP address information associated with the user from that endpoint is removed from the firewall.

Configuring one-to-one NAT

To configure one-to-one NAT on IPS:

1. Select **Endpoint Policy > Infranet Enforcer > Auth Table Mapping**.
2. Under One-One NAT deployment, enable the checkbox for **Provision Auth Table** for one-to-one NAT deployment.

Infranet Enforcer > Infranet Enforcer Auth Table Mapping Policies > AUTH PROV

☒ Provision Auth table for one-to-one NAT Deployment Enable this option to provision Auth Table for one-to-one NAT Deployment.

* indicates required field

3. The Admin is redirected to a confirmation page with a warning message.

This configuration option is recommended to use for one-to-one NAT Deployment. It is not recommended to use for many-to-one NAT Deployment. If used, it could allow multiple endpoints behind many-to-one NAT to access resources without authentication.

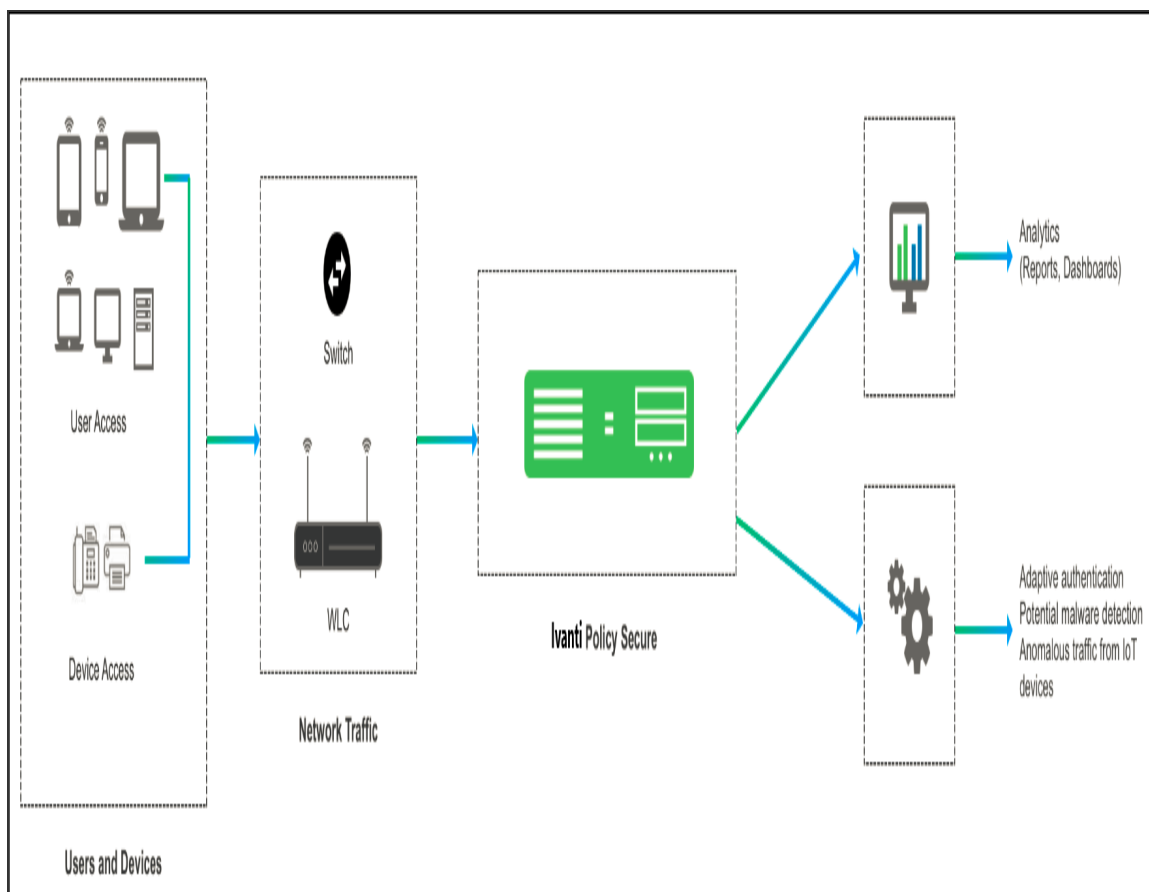

4. Click **Enable**.
5. Click **Save Changes**.

Behavioral Analytics

Overview

Enterprises deal with constant and ever-increasing magnitude of threat vectors, which includes Data Loss Prevention (DLP), malware and Domain Generation Algorithms (DGA) attacks. With changing business requirements and new types of threats, Administrators must understand how users and devices are accessing company's data and services to ensure that the access control policies are up to date. Even after successful authentication the user's activity should be monitored fully to ensure device compliance. Policy rules for protecting resources need to be configured and should be resistant to new attacks. Policy rules are configured manually, and the process is not scalable with new attacks. Hence, it is very important for Administrators to have insights into any anomalous behavior and act accordingly.

Behavioral Analytics feature analyzes user's action along with other context data to derive conclusions about any anomalous activities. It provides information/visibility based on real time user or device context thus helping in advanced attack detection and helps in proactive policy-based enforcement.

The Behavioral Analytics feature analyzes user or device behavior using the following methods:

- Adaptive Authentication- User/device is prompted for second level of authentication based on the threat profile determined for the corresponding user/device.

Below are some of the scenarios where second level of authentication is required:

- **User authenticating from new device:** This is detected by using the device MAC address.
- **User authenticating from new location:** Location details are obtained by using the subnet and location configurations.
- Anomalous Traffic from IoT devices: The unmanaged and IoT devices are profiled during the learning period configured in IPS. Any Anomalous traffic from these devices is detected as an anomaly based on the known profile of the device. IPS uses both Netflow and SPAN configuration on switches for detecting anomalous traffic from IoT devices.
- Potential Malware Detection: Malware on client devices have become more intelligent and in generating domain names by using dynamic generation algorithms. Hence, using rule-based policies might not detect these anomalies. IPS uses SPAN data collection method for monitoring DNS traffic and detects these potential malware on the endpoint.

Adaptive authentication user flow

- Users connect to IPS.
- IPS performs the primary authentication.
- IPS checks for any anomalies.
- IPS prompts for secondary authentication for the first login or if the user location changes.
- User enters the credentials required for secondary authentication.
- IPS performs the secondary authentication and allows/rejects access to the user/device.

Anomalous traffic from IoT devices user flow:

1. User/Device establishes a connection with IPS.
2. Switch and DNS Server forwards the network traffic of the device to IPS.
3. IPS analyzes the network traffic and takes the action based on the detected anomaly.

Potential malware detection user flow:

1. User/Device establishes a connection with IPS.
2. DNS server forwards all the domain resolutions to IPS.
3. IPS analyzes the DNS traffic and detects potential malware on the endpoint.

Licensing

- Adaptive Authentication feature is part of the IPS license.
- Anomalous Traffic detection from IoT devices and Potential Malware detection feature requires Behavioral Analytics license to be installed on IPS.

Benefits

- Monitors the traffic from user/devices and helps in determining the possible anomalous activities such as:
 - User is authenticating from a new device/new location.
 - Device traffic is different from previous instances.
 - Potential malware on the endpoint.
- Data collected as part of Behavioral Analytics is stored so that it can be used later for determining the anomalies.

Configurations

Pre-Requisites

IPS determines the network anomalies based on the NetFlow and Switch Port Analyzer (SPAN) configurations on the switch.

- Enable NetFlow (v5 or v9) and port mirroring/SPAN on switches. For sample configurations, see [Appendix](#).
- NetFlow traffic is currently qualified only with Cisco switches.

Summary of Configuration

1. Administrator enables the Behavioral Analytics feature and configures IPS based on the use case (Adaptive Authentication, anomaly traffic detection, potential malware detection). The Admin configures the list of switches in the network from where the network traffic can be received/forwarded to analytics engine on IPS.
2. Administrator configures the role mapping rules to consume these flags and control the access to the corresponding users and devices.
3. Administrator enables the secondary authentication for the users in case they are tagged with anomalies activities to ensure additional level of authentication for security purpose.
4. View the Dashboard and Reports for any detected anomalies.
5. From the Reports page, Administrator has options to clear the detected anomalies, export the available anomaly data to a CSV file.

- Behavioral Analytics configuration is synched across the nodes in the cluster (including config-only clusters). However, data collected and analyzed is synched across the nodes but not in case of config-only clusters.
 - RSPAN is the recommended configuration for cluster deployments especially for the Active/Passive cluster for seamless VIP failover.
 - Adaptive authentication is not supported for 802.1.x connections using native supplicant.
-

Configuring IPS for enabling Behavioral Analytics

For the fresh Installation of IPS, UEBA package will not be available by default for anomaly detection. Admin must add the UEBA package. In case of upgrade of IPS (R7 or earlier to R8 or later), the previous UEBA package is retained. You may download latest UEBA package from Ivanti Support Site (<https://my.pulsesecure.net>).

UEBA Package

To upload the UEBA package:

1. Log in to Ivanti Support Site, <https://my.pulsesecure.net>.
2. Select Ivanti Policy Secure as product and navigate to the "Ivanti Behavioral Analytics Database" section. Download the package, "ps-ics-ips-behavioral-analytics-v1.0.x.pkg".
3. From the Admin Console, select **System > Behavioral Analytics**.
4. Navigate to Browse and select the UEBA package.
5. Click **Upload & Activate**.
6. Click **Save Changes**.

Configuring IPS for Adaptive Authentication

To enable adaptive authentication:

1. Select **System > Behavioral Analytics > Configuration**.
2. Under Configurations, select **Enable Behavioral Analytics**.
3. For enabling Adaptive Authentication, select **Enable data collection** during authentication of devices and users.
 - For location-based anomaly detection, select **Enable subnet** based location anomaly detection.
4. Enter the Subnet details. For example, 10.11.1.2/24.
5. Enter the location name.
6. Type the location to search and press Enter.

7. Click **Add** to add the location.

☒ Enable Behavioral Analytics

☒ Enable data collection during authentication of devices and users

☒ Enable subnet based location anomaly detection

	Subnet	Location Name	Location

Configuring IPS to detect Anomaly Traffic from IoT devices

As a pre-requisite Profiler should have been configured for detecting the anomaly traffic from IoT devices. For more information, see *Profiler Deployment Guide*.

To determine anomaly traffic from IoT devices:

1. Select **System > Behavioral Analytics > Configuration**.
2. Under Configurations, select **Enable Behavioral Analytics**.

3. Select **Enable Network Traffic** from switches.
 - Configure the list of switches in the network from where the required data can be received/forwarded to analytics engine on IPS.
 - **Add the switches** manually by adding (Switch IP address/mac address) or add the existing switches under Add Switch from list table. Select **Dynamically add switches from RADIUS and SNMP** clients to automatically add switches from RADIUS and SNMP clients.
4. Select **Enable Data Collection through SPAN from switch to enable SPAN configuration** for determining unknown domain anomaly for unmanaged devices.
 - Select the network interface (External port/Internal port).
 - (Optional) Enter the IP address of the DNS server and click Add. DNS requests from these servers will not be considered for anomaly detection.

5. Enter the learning duration in days (7-30 days). Learning duration is learning period for unmanaged devices to build the device profile.

☒ Enable Network Traffic Monitoring from switches

Note: This is used for detection of Anomalous traffic from IoT devices

▼ Add switches manually

Add switches manually for monitoring netflow traffic.

Delete

↑

↓

Switch IP

Add

Example: 10.1.1.2 or 10.1.1.20/28 or fda6:f136:c4c7:5554::/64 or fda6:f136:c4c7:5554::

▼ Add switches from list

Add existing switches from the list which are configured as RADIUS or SNMP clients for monitoring netflow traffic.

Switch	IP	Type	Select
Cisco	10.1.1.6	Radius	<input checked="" type="checkbox"/>

☒ Dynamically add switches from RADIUS and SNMP Clients

Note: Selecting this option will automatically add switches from RADIUS and SNMP clients for monitoring network traffic.

☒ Enable data collection through SPAN from switch

Note: This is used for Malware detection and Anomalous traffic from IoT devices

Select Network Interface : External port

Note: The selected interface cannot be used for any other traffic.

DNS Servers

Add

10.0.0.14

Note: DNS requests from DNS servers will not be considered for domain anomaly detection. Example: 10.1.1.2

White listed domains

Add

Note: Whitelisted domains will not be considered as DGA attack domain. Ex: abc.com

Learning duration : 15 days

Number of days for which the system collects data for computing the baseline for an endpoint. The value should be between 7 to 30 days.

Save Changes

6. Click **Save Changes**.

Configuring IPS to detect Potential Malware

IPS relies on DNS traffic collected through SPAN to determine the potential malware on the endpoint.

To configure IPS for detecting potential malware:

1. Select **System > Behavioral Analytics > Configuration**.
2. Under Configurations, select **Enable Behavioral Analytics**.

3. Select **Enable Data Collection through SPAN** from switch to enable SPAN configuration for determining DGA based potential malware attacks. This anomaly detection mechanism is supported for both managed and unmanaged/IoT devices.
 - Select the network interface (External port/Internal port).
 - (Optional) Enter the IP address of the DNS server and click **Add**. DNS requests from these servers will not be considered for anomaly detection.
 - (Optional) Enter the white listed domains to exempt the domains from anomaly detection.

☒ Enable data collection through SPAN from switch
Note: This is used for Malware detection and Anomalous traffic from IoT devices

Select Network Interface: External port Note: The selected interface cannot be used for any other traffic.

DNS Servers	
<input type="text"/>	<input type="button" value="Add"/>
<input type="text"/>

5. Click **Save Changes**.

Dashboard and Reports

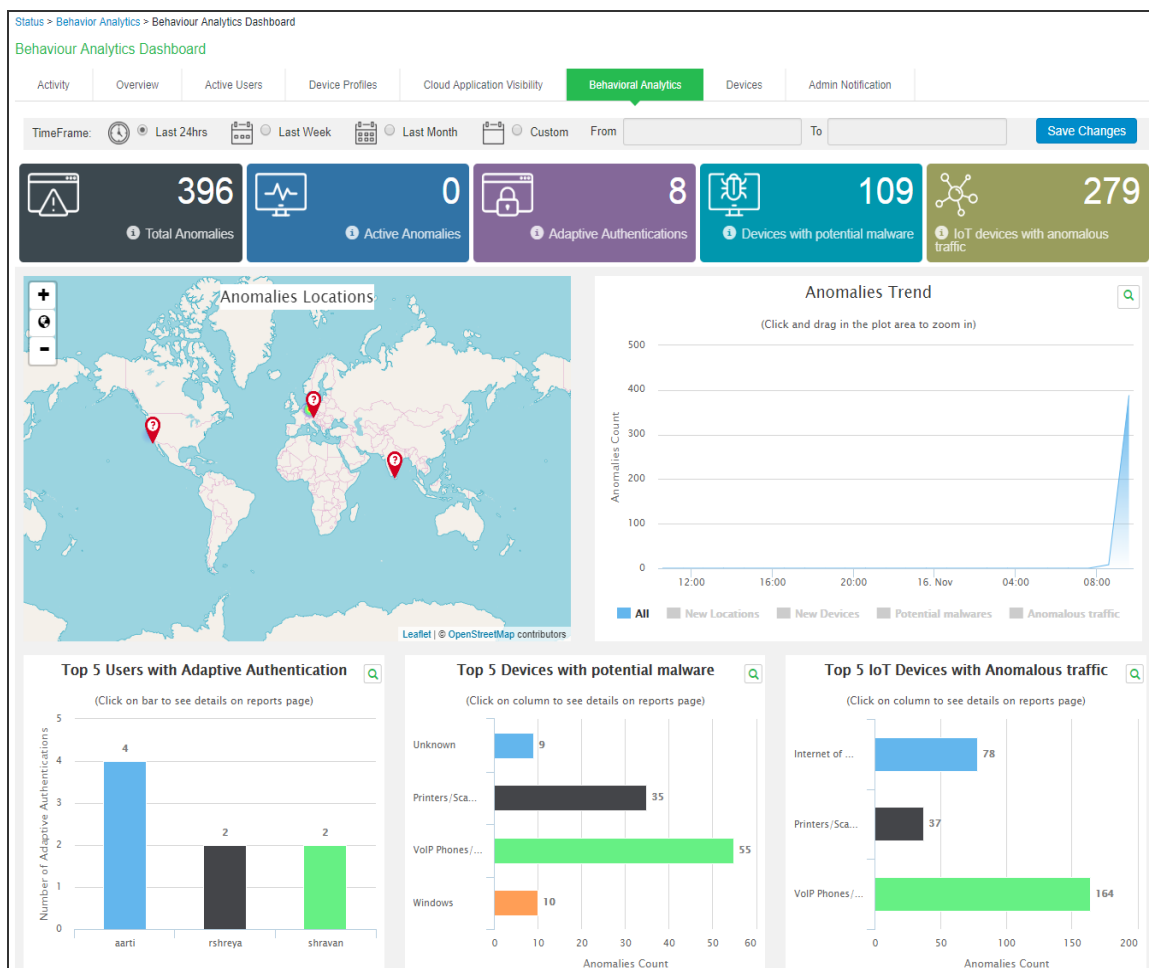

The Behavioral Analytics dashboard provides visibility to many anomalies in the network. It provides visibility of any known, active anomalies, devices with potential malware, IoT devices with anomalous traffic, anomalies location, trend and so on.

To view the Behavioral analytics dashboard:

1. Select **System > Status > Behavioral Analytics**.
2. Select the desired timeframe from available options.
3. Click **Save Changes**.

You can also view the drill down reports such as:

- Top 5 Users with Adaptive Authentication
- Top 5 Devices with Potential Malware
- Top 5 Devices with Anomalous Traffic

To view the Behavioural Analytics reports, select **System > Reports > Behavioral Analytics**.

Reports > Behavioral Analytics > Behavioral Analytics User Report

Troubleshooting

The event and debug logs can be used for troubleshooting:

The Event logs are generated for the device related anomalies:

- Anomalous traffic from IoT devices
- Potential malware

You can use the User Access and Admin Logs in case of any issues. The user access logs are generated whenever there are any user related anomalies such as user logging from new location/device/new user. The Admin Logs are generated whenever there is a change with Behavioral Analytics options and if there are any changes with respect to application policies.

You can also use **Maintenance > Troubleshooting > Monitoring > Debug Log** for debugging issues. Enable debug log with events *ueba*.

Appendix

SPAN

Switched Port Analyzer (SPAN) allows you to send a copy of traffic passing through ports to another port on the switch. SPAN is important to mirror received or transmitted (or both) traffic on one or more source ports to a destination port for analysis.

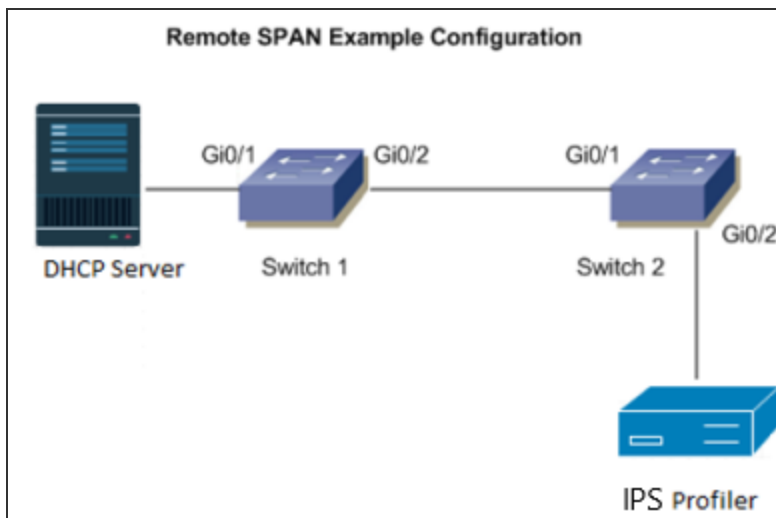

SPAN is mirroring ports in the same switch, RSPAN (Remote SPAN) is mirroring ports in one switch to a port in different switch.

This example describes how to configure RSPAN on Cisco Catalyst switches (Cisco 2960).

RSPAN

A sample topology to monitor traffic on port Gi0/1 in Switch1 using a IPS Profiler connected to port Gi0/2 in Switch2 is shown below.

Create a VLAN that will be used as an RSPAN-VLAN on both switches. In this example vlan ID 999 is used as the RSPAN-VLAN. Allow the RSPAN-VLAN on the trunk port between Switch1 and Switch2.

Switch1 (Source switch)

```
Switch1#conf t
```

```
Enter configuration commands, one per line.  End with CNTL/Z.
Switch1(config)#vlan 999
Switch1(config-vlan)#name RSPAN-Vlan
Switch1(config-vlan)#remote-span
Switch1(config-vlan)#exit
Switch1(config)#monitor session 1 source interface Gi0/1
Switch1(config)#monitor session 1 destination remote vlan 999
Switch1(config)#end
```

Allow VLAN ID 999 on the trunk port Gi0/2

```
Switch1#sh run int g0/2
Building configuration...
Current configuration : 175 bytes
!
interface GigabitEthernet0/2
description To-Switch2-port-Gi0/1
switchport trunk allowed vlan 74,999
switchport mode trunk
end
```

Switch2 (destination switch)

```
Switch2#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch2(config)#vlan 999
Switch2(config-vlan)#name RSPAN-Vlan
Switch2(config-vlan)#remote-span
Switch2(config-vlan)#exit
Switch2(config)#monitor session 1 source remote vlan 999
Switch2(config)#end
```

Allow vlan id 999 on the trunk port Gi0/1

```
Switch2#sh run int g0/1
Building configuration...
Current configuration : 175 bytes
!
interface GigabitEthernet0/1
description To-Switch1-port-Gi0/2
switchport trunk allowed vlan 10,20,30,999,60
switchport mode trunk
```

```
end
```

Allow VLAN id 999 on trunk port Gi0/2.

```
Switch1#sh run int g0/2
Building configuration...
Current configuration : 175 bytes
!
interface GigabitEthernet0/2
description To-Switch2-port-Gi0/2
switchport trunk allowed vlan 60,999
switchport mode trunk
end
```

NetFlow

NetFlow is a network protocol developed by Cisco for collecting IP traffic information and monitoring network traffic. Using a NetFlow collector and analyzer, you can see where network traffic is coming from and going to and how much traffic is being generated.

NetFlow V5 or V9 has to be configured on Cisco switch.

Commands on Cisco Switch

```
ueba-switch(config)#flow exporter UEBA
ueba-switch(config-flow-exporter)# destination <IPS IP>
ueba-switch(config-flow-exporter)#transport udp 2055
ueba-switch(config-flow-exporter)#export-protocol netflow-v9 (or
netflow-v5)
```

Cisco 3850 Catalyst switches support only v9 whereas Cisco 2960 supports both v5 and v9

```
ueba-switch(config)#flow record UEBA
ueba-switch(config-flow-record)# match ipv4 protocol
ueba-switch(config-flow-record)#match ipv4 source address
ueba-switch(config-flow-record)#match ipv4 destination address
ueba-switch(config-flow-record)# match transport source-port
ueba-switch(config-flow-record)#match transport destination-port
ueba-switch(config-flow-record)#match interface input
ueba-switch(config-flow-record)#collect interface output
ueba-switch(config)#flow monitor UEBA
ueba-switch(config-flow-monitor)#exporter UEBA
ueba-switch(config-flow-monitor)#cache timeout active 60
ueba-switch(config-flow-monitor)#record UEBA
```

```
ueba-switch(config)#interface GigabitEthernet1/0/3    --- (interface  
to which client endpoint is connected)  
ueba-switch(config-if)#ip flow monitor UEBA input
```

IoT Access

IoT Policy Provisioning

This chapter provides an overview of IoT device enforcement using SRX/PAN firewall.

Overview

As we increasingly connect devices to the Internet, new opportunities to exploit potential security vulnerabilities grow. Any unknown devices including IoT devices could serve as entry points for cyberattack by allowing malicious individuals to re-program a device or cause it to malfunction. The IoT devices are being added to corporate networks with or without the knowledge of IT administrator and they may communicate using the corporate IP network. These devices may have limited security controls leaving them open to be used as an attack vector. To improve security posture of IoT devices in corporate network, visibility and Role Based Access Control play a key role. Hence, it's extremely important to detect and classify what's there on the network.

IPS along with Profiler enables you to secure and manage access to IoT devices. It allows you to configure IoT Access Policy based on discovered or profiled device category. It also allows you to dynamically configure resource access policies for newly discovered devices and map user's role-based access to specific category and manufacturer or profile group of IoT devices.

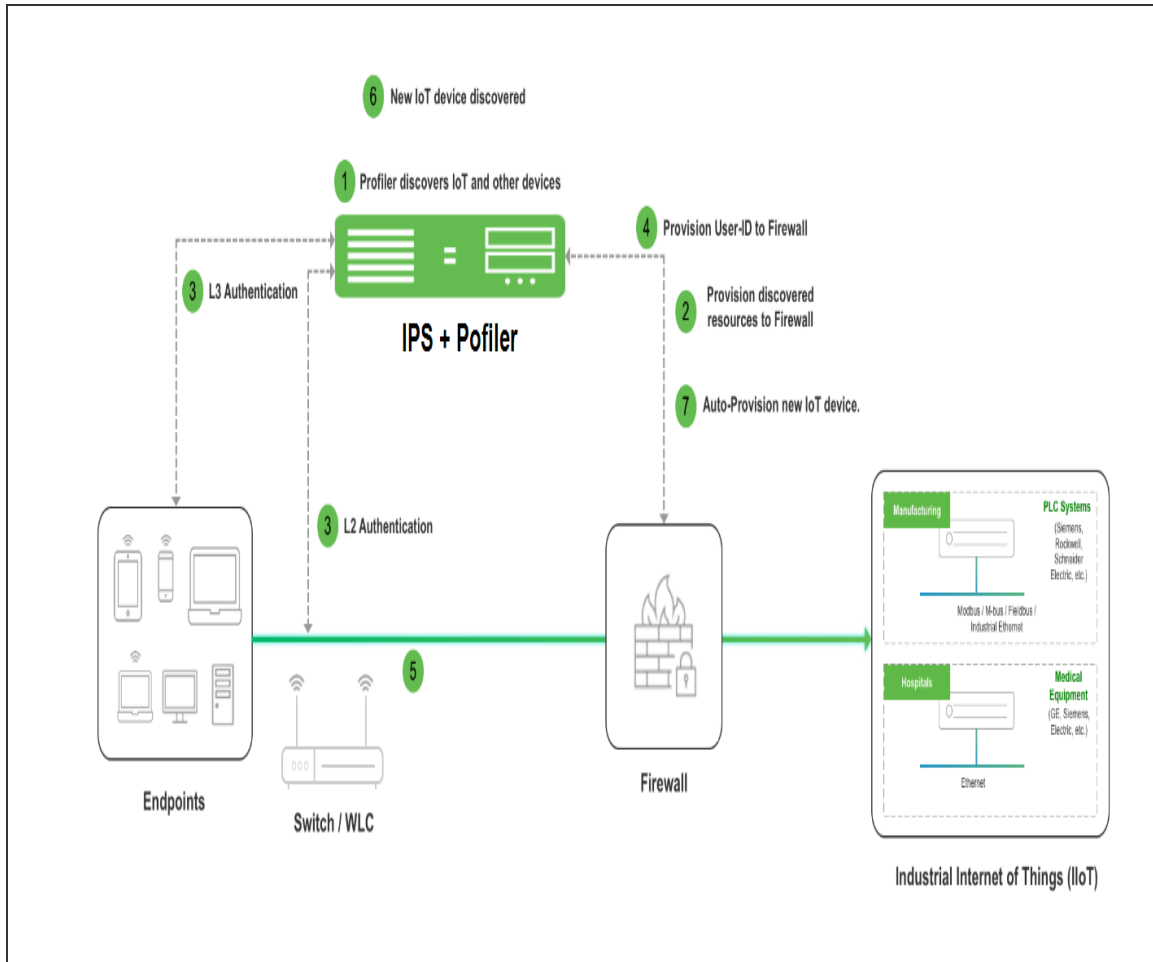

Benefits

The IoT Policy Provisioning Page enables you to quickly configure IoT policy provisioning and provides the following benefits:

- Discover and profile IoT devices using Profiler. Profiler enables you to continuously monitor the network and discover new devices such as security cameras, Industrial IoT devices (IIoT), and so on.
- IPS provides IoT access control using the IoT Access Policies, which are created automatically based on profiled or newly discovered device information from Profiler.
- Reduce IoT/IIoT machine downtime by allowing authorised users to get a role-based access to specific IoT/IIoT device for troubleshooting/maintenance.
- Automatic access control for the newly discovered IoT devices.

Deployments

The below network diagram depicts how IPS, Profiler, and SRX/PAN Firewall can be deployed to protect access to IoT devices. For example, the manufacturing domain consists of different IoT devices to monitor and control the manufacturing process. The industrial IoT devices are separated and controlled behind the firewall. IPS enables you to define IoT Access Policy using the Profiler attributes (category and manufacturer or profile group) and provides secure and seamless access to IoT devices for authorized users.

The workflow is described below:

1. A local Profiler configured on IPS discovers devices including IoT devices connected to corporate network.

2. IPS leverages the list of IoT devices discovered using Profiler and based on device category and manufacturer or profile group and it enforces or controls the access to IoT devices protected by the firewall.
3. User authenticates to IPS and endpoint compliance is evaluated. The user session is created on IPS and appropriate role is assigned based on the compliance check and user ID.
4. User Identity details (AuthTable) are provisioned to firewall.
5. User tries to access IoT devices protected by firewall. Authorised users (based on roles) are allowed to access IoT devices. Access to IoT devices by unauthorised users is blocked.
6. A new IoT device is added to the corporate network and same is discovered by Profiler.
7. IoT Access Policy for the newly discovered IoT device is automatically pushed to SRX/PAN firewall.

Only Local Profiler is currently supported.

The Administrator can group the discovered devices based on any Profiler attributes. For more information see, [Configuring Profiler Groups](#).

Configuring IoT Policy Provisioning

This section covers the procedure for configuring IoT Policy Provisioning on IPS.

Pre-Requisite

IoT Policy Provisioning requires Profiler feature. You must install the Profiler license on IPS to enable it.

Summary of Configuration

A high-level overview of the configuration steps needed to set up IoT Policy Provisioning is shown below.

Step 1: Configure Profiler

Step 2: Configure SRX/PAN Enforcer

Step 3: [Configuring IoT Access Policy](#)

Step 3.1: [Viewing Devices in Enforcer Policy Report](#)

Step 3.2: [Configuring IoT Access Policy using Juniper SRX Firewall](#)

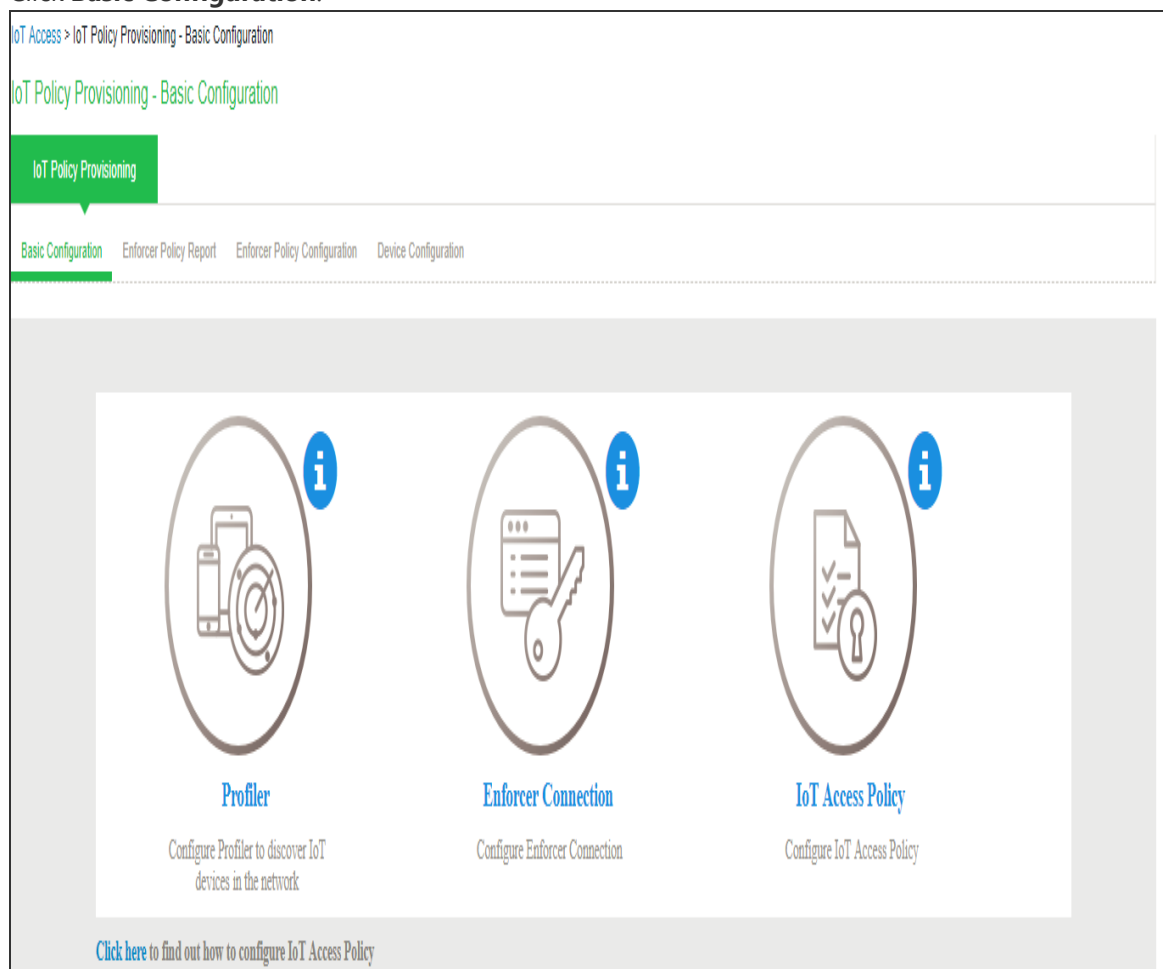

Step 4: Configuring Additional Device Category/Profile Groups

Basic Configurations

- The basic configuration page enables you to configure Profiler to discover IoT devices in the network,
- Enforcer to push the user identity information to IPS, and IoT Access Policy for IoT devices.

To launch the configuration page:

1. Select **Endpoint Policy > IoT Access > IoT Policy Provisioning**.
2. Click **Basic Configuration**.

If IPS is already configured with Profiler and Enforcer. The configurations will be reused.

- Configure the Profiler used to discover the IoT devices in the network. Click **Profiler** and configure the local Profiler. See *Profiler Deployment Guide* for complete configuration.
 - The icons in the configuration page indicate the status of configuration.
 - Green Tick mark refers that this section is configured correctly.
 - If the configuration section is in grey color, it indicates that the section is not configured.
 - Information icon refers that this section has to be configured.

Endpoints to scan using NMAP/VMES/SSH

Once devices are discovered using DHCP, SNMP or other mechanisms, more granular profiling is done only for those devices using NMAP, VMI and SSH active scan. Use the following subnet configuration to either allow, or disallow, such scans. Minimum 100 subnets

Subnet	Include/Exclude	Collector	Add
	<input checked="" type="radio"/> Include <input type="radio"/> Exclude	<input checked="" type="checkbox"/> NMAP <input type="checkbox"/> VMI <input type="checkbox"/> SSH	

Subnets should be in valid CIDR format or individual IP or IP Range.
 Example Subnets:
 Valid CIDR Format:
 192.168.1.0/24
 10.200.0.0/16
 IP or IP Range:
 10.10.10.10
 10.10.10.10-100
 10.10.1.1-10.10.5.200

VM Profiling

Configuring IoT Access Policy

Viewing Devices in Enforcer Policy Report

This page provides details of discovered and connected IoT device's and firewall policies applied for IoT devices. You can view details such as total number of IoT devices, number of IoT devices enforced, number of IoT devices not enforced, and IoT device manufacturers.

To view the enforcer policy report:

1. Select **Endpoint Policy > IoT Access > IoT Policy Provisioning**.
2. Click **Enforcer Policy Report**.

Configuring IoT Access Policy using Juniper SRX Firewall

The IoT access policy specifies which users are allowed or denied access to a set of protected resources. You can specify which users you want to allow or deny by choosing the roles for each IoT Access Policy. The IoT Access Policy page enables you to configure the policy based on device details using Profiler device attributes, such as device category and manufacturer or profile group.

When the network Administrator selects category and manufacturer or profile group information under device details the IP addresses of the corresponding discovered devices get automatically updated under Resources. Hence the Administrator can seamlessly create IoT Access Policy of profiled devices based on device category, device manufacturer attributes, or Profiler group. If the Administrator wants to have granular control over the IoT devices, further control can be achieved by providing specific port and protocol. The specified port and protocol configuration is applied to all the discovered devices of the selected category and manufacturers.

To configure IoT access policy:

1. Select **Endpoint Policy > IoT Access > IoT Policy Provisioning > Enforcer Policy Configuration**.
2. Click **New Policy**.
3. Enter the Policy name.
4. Enter a description.
5. Under Infranet Enforcer, select the Platform as **Junos SRX**.

6. Under **Device Details**, specify whether the policy should be applied based on device category and manufacturer or Profile group.

- Category and manufacturer
 - Specify the category from the drop-down list. The values in the drop-down list is populated based on the Device category configuration (IoT Access > IoT Policy Provisioning - Device Configuration).
 - Select the Device manufacturer from the Available Device Manufacturers.
 - Specify the protocol (TCP/UDP/ICMP) and Port/Range to be applied to the discovered devices.
- Profile Group
 - Configure the Profiler Group (IoT Access > IoT Policy Provisioning - Device Configuration). To configure Profiler Groups, [Configuring Profiler Groups](#).
 - Select the Profile Group from the Available Profile Groups.
 - Specify the protocol (TCP/UDP/ICMP) and Port/Range to be applied to the discovered devices.

Port ranges must be configured in dash-separated, comma-delimited, ascending, and non-overlapping order. Multiple port ranges must be separated by a comma. For example, the following examples show the delimiters that are used to enter port ranges:(80, 443, 1-1024, 1-100, 500-600).

The Port/Range entered will be applied to all the discovered devices. If you want to enter different port values, you can edit the port value under Resources table.

- Select **Auto-Update Newly Discovered** Devices to automatically add IoT Access Policy for the newly discovered devices from the selected category and manufacturer or **Profile Group**.

For example, If a policy is created for IoT device category with manufacturer or Profile Group with **Auto-Update** Newly Discovered Devices enabled then for any new IoT device discovered with the selected manufacturer, a IoT Access Policy is automatically added to firewall. If port and protocol are specified in the "Device Details" panel, the policy for the newly discovered devices is applied for specified port and protocol.

7. Under Resources, the IoT devices will be auto populated using the Device details configuration described earlier. If the administrator wants to apply policies on different ports for different discovered devices, the port configuration can be edited. If the Admin selects multiple protocol (for example, TCP and UDP) then the device entries appear twice with protocol information in the Resources table. The Admin can choose whether to push the policies for the selected resource based on the IP address, Protocol, and Port information to enforcer by enabling/disabling the checkbox in the resources table.
8. Select the desired Roles for which the policy applies. For example, IoT Administrator.
9. Under Actions, select whether to allow access or deny access.

10. Click **Save Changes**.

IoT Access > IoT Policy Provisioning > Enforcer Policy Configuration > iot-group

iot-group

General

* Name: iot-group Required: Labeled to reference this policy.

Description:

▼ Intranet Enforcer

Platform: ☒ JUNOS SRX ☐ Palo Alto Networks Firewall

Specify the Intranet Enforcer(s) to which this policy applies.
(Applicable for only Juniper and Palo Alto Networks Firewalls.)

Available Enforcers: SRX_Cluster (SRX)

Selected Enforcers: SRX650_89_109 (SRX)

▼ Device Details

Specify the filter for getting resources.

☐ Category and Manufacturer ☒ Profile Group

Click here to configure Device Category or Profile Group.
Select the profile group(s) for which this policy applies.

Available Profile Group(s):

Selected Profile Group(s): iot-group 1

Specify Protocol and PortRange which will be applied to the discovered devices.

Protocol: ☒ TCP ☐ UDP ☐ ICMP

Port: Examples: 80 or 80,433 or 1-1024 or 8080, 1-1024,8082 or 1-1024,8080 or 1-100,500-600 etc.

☒ Auto-Update Newly Discovered Devices.

▼ Resources

Resources will be auto-populated using the configuration specified in Device Details panel, port field is editable.
Policy for the selected resources will be pushed to enforcer.

i The Device Details panel is only available when IoT Access Policy is created using IoT Policy Provisioning > Enforcer Policy Configuration.

Configuring IoT Access Policy using Palo Alto Networks Firewall

The IoT access policy specifies which users are allowed or denied access to a set of protected resources. You can specify which users you want to allow or deny by choosing the roles for each IoT Access Policy. The IoT Access Policy page enables you to configure the policy based on device details using Profiler device attributes, such as device category and device manufacturer or Profile Group.

When the network Administrator selects category and manufacturer or Profile Group information under device details the IP addresses of the corresponding discovered devices get automatically updated under Resources. Hence the Administrator can seamlessly create IoT Access Policy of profiled devices based on device category, device manufacturer attributes, or Profiler group. If the Administrator wants to have granular control over the IoT devices, further control can be achieved by providing specific port and protocol. The specified port and protocol configuration is applied to all the discovered devices of the selected category and manufacturers.

To configure IoT access policy:

1. Select **Endpoint Policy > IoT Access > IoT Policy Provisioning > Enforcer Policy Configuration**.
2. Click **New Policy**.
3. Enter the Policy name.
4. Enter a description.
5. Under Infranet Enforcer, select the Platform as **Palo Alto Networks Firewall**.
6. Under Security Zones, specify the firewall security zones (source zone/destination zone) for the policy. Multiple zones can be specified with comma separated values. If zones are not specified, then it applies to all zones.
7. Under Service, select any to allow all TCP and UDP ports (default) or select the service to specify the TCP or UDP port or port range. The policy port and protocol configuration remains same for all the resources.

8. Under **Device Details**, specify whether the policy should be applied based on device category and manufacturer or Profile group.

- Category and manufacturer
 - Specify the category from the drop-down list. The values in the drop-down list is populated based on the Device category configuration (IoT Access > IoT Policy Provisioning - Device Configuration).
 - Select the Device manufacturer from the Available Device Manufacturers.
 - Specify the protocol (TCP/UDP) and Port/Range to be applied to the discovered devices.
- Profile Group
 - Configure the Profiler Group (IoT Access > IoT Policy Provisioning - Device Configuration). To configure Profiler Groups, see [Configuring Profiler Groups](#).
 - Select the Profile Group from the Available Profile Groups.
 - Specify the protocol (TCP/UDP) and Port/Range to be applied to the discovered devices.

Port ranges must be configured in dash-separated, comma-delimited, ascending, and non-overlapping order. Multiple port ranges must be separated by a comma. For example, the following examples show the delimiters that are used to enter port ranges: (80, 443, 1-1024, 1-100, 500-600).

The Port/Range entered will be applied to all the discovered devices.

- Select **Auto-Update Newly Discovered Devices** to automatically add IoT Access Policy for the newly discovered devices from the selected category and manufacturer or Profile Group.

For example, If a policy is created for IoT device category with manufacturer or Profile Group with **Auto-Update Newly Discovered Devices** enabled then for any new IoT device discovered with the selected manufacturer, a IoT Access Policy is automatically added to firewall. If port and protocol are specified in the "Device Details" panel, the policy for the newly discovered devices is applied for specified port and protocol.

9. Under **Resources**, the IoT devices will be auto populated using the Device details configuration described earlier. If the administrator wants to apply policies on different ports and protocols for different discovered devices, the port configuration can be edited. If the Admin selects multiple protocol (for example, TCP and UDP) then the device entries appear twice with protocol information in the Resources table. The Admin can choose whether to push the policies for the selected resource based on the IP address, Protocol, and Port information to enforcer by enabling/disabling the checkbox in the resources table.
10. Select the desired Roles for which the policy applies. For example, IoT Administrator.
11. Under **Actions**, select whether to allow access or deny access.
12. Click **Save Changes**.

IoT Access > IoT Policy Provisioning > Enforcer Policy Configuration > New Policy

New Policy

Name: IoT1 Required: Label to reference this policy.

Description:

Intranet Enforcer

Platform: ☐ JUNOS SRX ☒ Palo Alto Networks Firewall

Specify the Intranet Enforcer(s) to which this policy applies.
(Applicable for only Juniper and Palo Alto Networks Firewalls.)

Available Enforcers: PAN_88.234 (PANNGFW)

Selected Enforcers: PAN-10.96.70.1 (PANNGFW)

Security Zones

Specify firewall security zones for this policy.
If security zone is not specified, then it applies to all zones (i.e. any).
Multiple zones can be specified with comma separated. Example: trust,mgmt

Source Zone: untrust

Destination Zone: trust

Device Details

Specify the filter for getting resources.

☐ Category and Manufacturer ☒ Profile Group

Click here to configure Device Category or Profile Group.

Select the profile group(s) for which this policy applies.

Available Profile Group(s):

Selected Profile Group(s): iot-group1

Service: any

☒ Auto-Update Newly Discovered Devices.

Resources

Resources will be auto-populated using the configuration specified in Device Details panel; port field is editable.
Policy for the selected resources will be pushed to enforcer.

Resource Access Policy and IoT Policy Provisioning with Palo Alto Network's Firewall works only with default Virtual System "vsys1" and default device name "**localhost.localdomain**" configuration.

Configuring Additional Device Category/Profile Groups

- The Internet Of Things (IoT) device category is selected by default and hence it is visible by default on IoT policy enforcer report and Policy Configuration page. However, If the Administrator wants to use IoT Policy Provisioning feature for other Profiler supported categories such as Video Conferencing Devices, Printers/Scanners, Medical device, Storage device and so on additional categories can be configured on this page.

- Under Profile Groups, Admin can select the groups that should be used with IoT Policy Provisioning feature. Only the selected Profile Groups are shown while creating IoT access policy using Profile Groups. If none of the Profile Groups are selected in Device Configuration tab then no groups are shown in IoT access policy. To create IoT access policy using Profile Groups, the same needs to be selected in the Device Configuration tab.

Save Changes

Configuring Profiler Groups

Administrator can create different Profile Groups by using different Profiler attributes (for example, group all IoT devices with manufacturer Schneider Electric and Operating System Linux) and combine discovered devices in a group. If an Admin wants to provision IoT Access policy using attributes other than Category and Manufacturer, a Profile Group can be created to group discovered devices and then IoT Policy Provisioning feature can be used for the resources belonging to Profile Group.

To configure Profiler Groups:

1. Select the Profiler server under **Authentication > Auth. Servers**.
2. Select **Profile Groups** tab, select the **New Profile Group**.
3. Enter the **Group Name** and **Rule**. The rules can be written with device attributes and suggested operators can be chosen from the list.
4. As an optional step, emails also can be configured which results in notifications for any group related changes.

5. Click **Save Changes**.

Troubleshooting

The event and debug logs can be used for troubleshooting:

- The Event logs are generated whenever the policies are pushed to firewall.
- The Admin Logs are generated upon policy provisioning and auto updation of newly discovered devices.

You can also use **Maintenance > Troubleshooting > Monitoring > Debug Log** for debugging issues.

If the device is not discovered properly in the IoT Policy Provisioning > Enforcer Policy Report page check the Device Discovery Report page for the device category.

The IPS created policies on PAN firewall should not be modified by the PAN admin. The IPS created policies on Palo Alto Networks firewall are tagged as *Pulse Secure Managed*.

Host Checker

Host Checker Overview

Host Checker is a software component that performs endpoint compliance checks on hosts that connect to the IPS. It supports two types of rules within a policy; predefined and custom. The predefined inspection capabilities consist of health and security checks including antivirus versions, antispyware, OS versions, hard disk encryption status and patch checks. The pre-defined rules are provided by OPSWAT and it uses the ESAP plug-in for pre-defined checks. For more information, see Endpoint Security Assessment Plug-In (ESAP).

Custom rules allows admin to define checks to collect system health using Integrity message collector (IMC) and evaluate using Integrity message verifier (IMV) of TNC framework. The custom rules are created by the admin to include inspection checks such as absence or presence of specific file, certificate checks, TCP ports, processes, registry key settings, NetBIOS name, MAC addresses or certificate of the client machine and third party inspection methods (custom DLLs).

Host Checker evaluation is done at 2 stages:

1. Initial check or evaluation of the user machine as the user browses to the sign-in page.
2. Enforcement of the policy during the user sign-in process, which happens at realm or role level.
 - **Realm-level policies/Pre-Authentication**— The realm level policy is also called as Pre-Authentication requirement as it occurs before the user is prompted for authentication.
 - **Role-level policies/Post-Authentication**—The role level policy is also called as Post-Authentication requirement as it occurs after the user is authenticated and during the role-mapping phase.

If the endpoint does not meet HC policy requirement, administrator can define a customized remediation page with specific instructions and links to resource to ensure that the end user's computer is compliant with the HC policy.

Host checking for layer 2 session is supported only for Ivanti initiated 802.1x session. Note that it's not supported for session initiated by native supplicant. For layer 3 sessions host checking is supported Ivanti initiated and browser based sessions.

Trusted Network Connect

Host Checker is compliant with the Trusted Network Connect (TNC) model developed by Trusted Computing Group (TCG). TCG created an architecture and set of standards for verifying endpoint integrity and policy compliance during or after a network access request. For more information about TNC, see www.trustedcomputinggroup.org.

Policies

Ivanti Policy Secure(IPS) Host checker component supports many different type of product policy evaluation on endpoint along with continues monitoring of system health. The below table lists the description of various policies and features, which can be defined as part of device compliance check.

Policy	Description
Predefined	
Antivirus Policy	Policy to detect whether the Antivirus is installed and up-to-date with latest virus signatures. It also includes other options to check the last scan time, virus signature download, and remediation options.
Firewall Policy	Policy to detect the firewall installed on endpoint and the remediation option to turn on the firewall if it's turned off.
Anti-Spyware Policy	Policy to detect the installed spyware on endpoints.
Hard disk Encryption	Policy to detect and check the encryption status of the specified or all drives using installed encryption software.
Patch Management	Policy to check whether the required operating system patches are installed properly.
OS Checks	Policy to check the version of the windows operating systems and minimum service packs.
Common Vulnerability and Exposure (CVE)	Policy to check any vulnerable attacks such as ransomware attack.
System Integrity Protection (SIP)	Policy to check the status (enabled/disabled) of System Integrity Protection (SIP) on the Mac OS endpoints.
Custom	

Policy	Description
3rd Party NHC Check	Policy to specify the location of custom DLL files.
Ports policy	Policy to check if a particular port is either opened or closed to allow or reject the user authentication.
Process policy	Policy to control the software or processes that runs on the client machine.
File Policy	Policy to check if a particular file with specific version or checksum, or last modified file is present on endpoint to allow or reject the user authentication.
Registry Settings policy	Policy to check the registry and its value to allow or reject the user authentication, with a remediation option to set the registry value if not configured.
NetBIOS policy	Policy to check the NetBIOS name from list of NetBIOS names provided to control user access.
MAC Address policy	Policy to check if the endpoint MAC address is in the provided regex or white listing of mac addresses to control user access.
Machine Certificate Policy	Policy to check for the required machine certificate on the endpoint to control user access. This policy evaluates both public and private keys of the installed machine certificate on endpoint for users using Ivanti Secure Access Client. For agentless users, only public key is evaluated.
Advanced Host Checking	Policy to dynamically check the compliance status of the endpoints. It includes combining 2 policy types for obtaining the expected values of the check type. The expected values are fetched from registry location on the client machine for evaluating the policies. The advanced support for checking the expected values against another policy is supported on Ports, Process, File, Registry, NETBIOS, MAC Address, and Machine certificate.
Statement of Health	Policy to perform the health state validation to determine which roles or realms can be accessed by endpoints. It checks the system health indicators such as antivirus is enabled and up to date, antispysware is enabled and up to date, firewall is enabled and so on.

Policy	Description
Command	Policy to check the versions of the installed applications on the Mac OS endpoints.
Host Checker General Settings	IPS provides following admin configuration options while performing host checking.
General Options	
Continuous Policy Evaluation	Option to configure periodic and continuous policy evaluation so that the endpoint is compliant with the Host Checker policy.
Virus Signature Version Monitoring	Option to monitor and verify the virus signatures, operating systems, and patches installed are up to date.
Pre-Authentication Host Checking	Pre-Authentication host checking are policies that are enforced at the realm level before authentication.
Post-Authentication Host Checking	Post-Authentication host checking are policies that are enforced when role assignment happens after authentication.

Agent and Agentless Host Checking

Agentless Host Checking means endpoints trying to connect IPS through browser (User Agent should be a browser such as Google Chrome, Edge, Internet Explorer, Firefox ESR). Agent based Host Checker means endpoints trying to connect to IPS through Ivanti Secure Access Client.

You can also see [KB44716](#) for differences between agent and agentless Host Checking.

Agentless	Ivanti Agent
Agentless solution refers to endpoints connecting to network using web browser. With Agentless solution, the device has to get the layer 3 access using an IP address.	Ivanti Agent solution refers to endpoints connecting to network using Ivanti Secure Access Client. With Ivanti agent, the user never gets the full connection to the network during the validation cycle. The connection validations are performed at Layer 2 without requiring the device access the network.

Agentless	Ivanti Agent
Agentless solution polls the network on a regular basis to check whether the endpoint is compliant. The user has to enable security protections at the beginning of the cycle to avoid any network breach.	Ivanti agent always performs continuous monitoring. Any changes to security measures are identified in the real time and thus strengthens the network security posture.
Agentless solution inspects the endpoints using WMI protocol.	Ivanti Agent uses more secured protocols.

Support Platform Matrix

A Host Checker policy contains one or more rules. Each rule can apply to different host checks and for different device types (Windows, Mac, Linux, iOS, Android). The below table lists the Host Checker policies that are supported on Windows, Mac and Linux.

Policy	Windows		Macintosh		Linux	
	Client	Clientless	Client	Clientless	Client	Clientless
Antivirus	Yes	Yes*	Yes	Yes*	No	No
Firewall	Yes	Yes*	Yes	Yes*	No	No
AntiSpyware	Yes	Yes	Yes	Yes	No	No
Hard Disk Encryption	Yes	Yes	Yes	Yes	No	No
Patch Assessment	Yes	Yes	Yes	Yes	No	No
OS Checks	Yes	Yes	Yes	Yes	No	No
Common Vulnerability and Exposure (CVE) Check	Yes	Yes	No	No	No	No

Policy	Windows		Macintosh		Linux	
3rd Party NHC Checks	Yes	Yes	No	No	No	No
Ports	Yes	Yes	Yes	Yes	Yes	Yes
Process	Yes	Yes	Yes	Yes	Yes	Yes
Files	Yes	Yes**	Yes	Yes**	Yes	Yes**
Registry Setting	Yes	Yes***	No	No	No	No
NetBIOS	Yes	Yes	Yes	Yes	No	No
MAC Address	Yes	Yes	Yes	Yes	No	No
Machine Certificates	Yes	Yes****	Yes	Yes	No	No
Statement of Health	Yes	Yes	No	No	No	No
System Integrity Protection (SIP)	No	No	Yes	Yes	No	No
Command	No	No	Yes	Yes	No	No
Advanced Host Checking	Yes	Yes	No	No	No	No

- * In some occasions, Antivirus/Firewall products restricts the remediation actions to admin/services (For example but not limited to, turning on firewall). In such scenarios, certain remediation actions won't work with browser/clientless logins. Note that, this is defined by the corresponding security products.
- **Admin should enable system level access for accessing certain files and file locations for browser login.
- ***To access device-certificates from system store, the plugin needs admin rights. With browser/clientless login private key verification is not supported in Agentless login.
- ****Registry verification requires admin privileges for accessing certain registry files. There are limitations with accessing some of the registry hierarchy for evaluating registry checks for browser login.
- Agentless mode with Profiler is supported only with Windows platforms. The supported policies are Antivirus, Firewall, Antispyware, OS checks, Ports, Process, NetBIOS, and MAC Address. For more information, see Profiler documentation.

Host Checker Remediation Capabilities

	Windows	Mac OS	Linux
Custom Instructions	Yes	Yes	Yes
Custom Actions	Yes	-	-
Kill Process	Yes	Yes	Yes
Delete Files	Yes	Yes	Yes
Reason String	Yes	Yes	Yes

Host Checker Installation Options

Host Checker is supported for agent and agentless clients. The installation options are listed below:

- Browser based Host Checking (Agentless) — This is used for browser-based logins and requires PSAL to be present on the endpoint. If PSAL is not available on the endpoint, it gets installed as part of the connection.

- It is recommended not to keep a very low value for **login inactivity timeout** (For example, 1 or 2 minutes). This might result in connection timeouts on fresh endpoints where PSAL also need to be installed as part of compliance evaluation.
- Ivanti Secure Access Client (Agent)—You can use Ivanti Secure Access Client, which contains the Host Checker component for compliance check. To manually install the Host Checker, Select **Maintenance > System > Installers** and download the Pulse installer.

Using the downloaded executable file, you can:

- Distribute the file to client machines using software distribution tools. This option enables you to install an application or service on client machines.
- Post the executable in a secure repository so that users with the proper administrator right may download and install the appropriate version.

Auto-upgrading Host Checker

To automatically upgrade Host Checker:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Under Options, select **Auto-upgrade Host Checker** if you want the system to automatically download the Host Checker application to a client computer when the version of Host Checker on the system is newer than the version installed on the client.
3. Click **Save Changes**.

Endpoint Security Assessment Plug-In (ESAP)

The Endpoint Security Assessment Plug-in (ESAP) is a plug-in in IPS using which you can upload the latest SDK from Opswat independently.

Ivanti frequently adds enhancements, bug fixes, and support for new third-party applications to the plug-in. New plug-in releases are available independently and more frequently than new releases of the system software package. If necessary, you can upgrade the plug-in independently of a system upgrade.

You can upload up to four versions of the plug-in, but the system uses only one version at a time (called the active version). If necessary, you can rollback to a previously active version of the plug-in.

If the endpoints in your deployment connect to multiple servers simultaneously, all of those connected servers must use the same version of the ESAP plug-in.

Upgrading the ESAP

1. To upgrade the ESAP plug-in:
 - Download the Endpoint Security Assessment Plug-in from the [Ivanti Support Portal](#).
 - To access the Customer Support Center, enter a username and password for a Ivanti Support Center account.
 - Click the ESAP Download Page link.
 - Navigate to the ESAP release you want.
 - Download the plug-in zip file to your computer.
2. Select **Authentication > Endpoint Security > Host Checker**.
3. On the Host Checker page, under Manage Endpoint Security Assessment Plug-In Versions:
 - If you want IPS to actively begin using the new component software immediately after you upload it, select the Set as active after upload option.
 - Click **Browse**, select the plug-in file to upload and click **OK**.
 - Click **Upload**. After the plug-in is installed, the date and time of the plug-in installation is displayed in the plug-in list.
 - If you did not select the Set as active after upload option, activate the plug-in to use by selecting the version in the plug-in, list and click **Activate**.

- You can rollback to an older plug-in version after you upgrade to a later version by selecting the older version as the active version.

- If you upgrade the system software to a newer version, or if you import a user configuration file, active plug-in version can change based on the supportability of ESAP version. If you want to use a different plug-in version after you upgrade or importing a user configuration file, you must manually activate that plug-in version.

OPSWAT SDK V3 to V4 Migration

Ivanti supports Opswat version 3 and version 4 for endpoint compliance evaluation. The migration option helps the administrators to migrate their servers and clients with Opswat v4 to take advantage of latest updates.

Software Support- Starting with Release 9.1R2 and later releases.

OS support: Windows 7 and later releases and macOS 10.12 and later releases

Prerequisites - ESAP 4.0.5 is the minimum version. A warning message is displayed if the minimum version is not present.

Procedure to migrate from Opswat V3 to V4

To migrate follow the below procedure:

1. Navigate to “**Manage Endpoint Security Assessment PlugIn Versions**” section on **Authentication > Endpoint Security > Host Checker** page.
2. Enable the option for **Enable migration of Opswat SDK from old to new version (V3 to V4)**.

3. On enabling this option, the clients start downloading the **V4 SDK and migrate to newer SDK**.

▼ Manage Endpoint Security Assessment Plugin Versions

Currently Active ESAP version: 3.4.2
Default ESAP version: 3.3.5

10 records per page Search:

	Version	Uploaded	Last Activated
<input type="radio"/>	3.3.5	Fri Jun 14 00:19:55 2019	Mon Jun 17 13:04:54 2019
<input type="radio"/>	3.4.2	Mon Jun 17 12:47:52 2019	Mon Jun 17 13:05:11 2019

← Previous 1 Next →

☒ **Enable migration of Opswat SDK from old to new version (V3 to V4)**

Note: Enabling this option starts Opswat SDK V3 to V4 migration on the client machines. This option enforces V3 Opswat SDK usage in host checker policy definitions by enabling Older SDK usage option below, so that host check happens properly irrespective of whether client machine has Opswat V3 or V4 SDK installed. During the next host check on the client machine, Opswat V4 SDK will be installed. Minimum ESAP version '3.4.2' is needed for supporting this migration.

☒ **Activate Older Opswat SDK in ESAP for Host checker policy evaluation.**

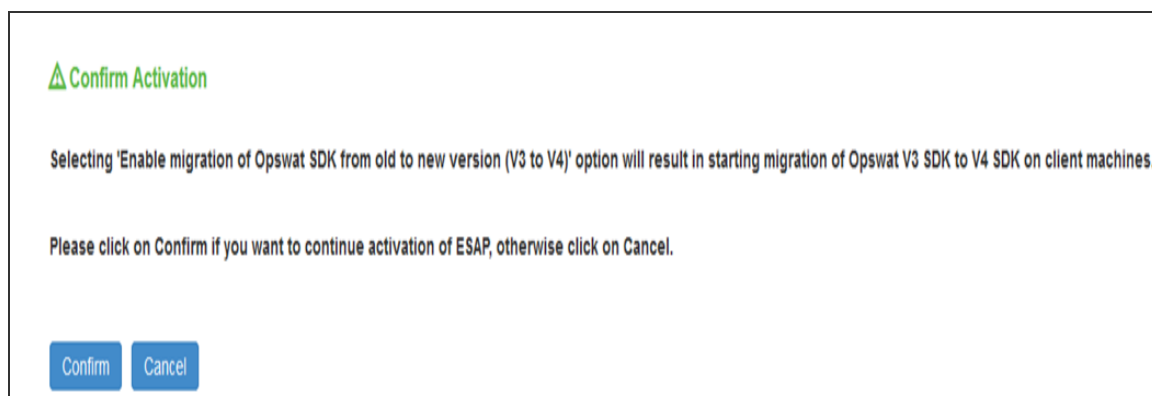

Note: ESAP contains two versions of Opswat SDKs for supporting policy evaluation. It is recommended to use the newer version of the Opswat SDK. Use the older version if you have Pulse Clients before 5.2R5, Pulse Connect Secure appliances before 6.2R5, or Pulse Policy Secure appliances before C5.3R5.

☐ **Enable Active ESAP package on the client**

Note: Enabling this option ensures that the active ESAP package is used on all the client machines. If the client machine contains a newer ESAP package it will be replaced with the active ESAP version.

Package: No file chosen ☐ Set as active after upload

4. **Uncheck/Disable Enable migration of OPSWAT SDK from old to new version (V3 to V4)** option once the migration is complete. Verify the migration status.
5. A confirmation message display. Click **Confirm**.

Post migration, Admin can remap the configured products in the policies to map to the newer SDK using the post migration window.

For example, in the below screenshot the Product /Vendor Name for the policy has been changed from Microsoft Corp. to Microsoft Corporation for successful migration.

Confirm Activation

Deselecting 'Enable migration of Opswat SDK from old to new version (V3 to V4)' option will result in stopping migration of Opswat V3 SDK to V4 SDK migration on client machines.

Deselecting 'Activate Older Opswat SDK in ESAP for Host checker policy evaluation' option will result in using newer version of Opswat SDK on client machines.

The current configuration contains the following list of products and/or vendors that are no longer supported in ESAP version '3.4.2'. These items will be automatically deleted from the corresponding Host Checker rules upon ESAP activation.

10 records per page Search:

Policy Name:	Platform:	Rule Name:	Rule Type:	Product/Vendor Name:	New Product/Vendor Name(s):
Advanced_HC	Windows	Rule-3	Specific Vendor	Microsoft Corp.	Microsoft Corporation

Showing 1 to 1 of 1 entries ← Previous 1 Next →

We have detected that the following host checker rules may become empty due to above mentioned deletion. Empty Host Checker (HC) rules will always be evaluated as failed and may cause the host checker policy to fail. We strongly recommend that these empty HC rules be deleted manually after ESAP activation.

Policy Name:	Platform:	Rule Name:	Rule Type:
Advanced_HC	Windows	Rule-3	Specific Vendors

☒ Backup 'User Configuration' and 'XML containing configured Host Checker, Realms and Roles details'

Note: A backup of User Configuration and XML containing Host Checker policies, Realms and Roles details will be created under 'Maintenance->Archiving->Local Backups'
This may take several minutes (depends on configuration of the server)

Please click on Confirm if you want to continue activation of ESAP, otherwise click on Cancel.

Confirm **Cancel**

6. Enable **Backup User Configuration** and XML containing **Host Checker, Realms** and **Role details for performing configuration backup**. This option helps to revert to the previous version of IPS/ICS configuration, if required.
7. Click **Confirm**.

Compliance Report

The Compliance Report displays the compliance details of the users connected to the server. The report also includes the Opswat SDK Version used for these connections. **Opswat SDK Version** is used to filter the users using a specific Opswat SDK version.

The compliance report page displays the Opswat SDK version details only when "Enable migration of OPSWAT SDK from old to new version (V3 to V4)" option is enabled.

To check the SDK version for each connection, view the report under **System > Reports > Compliance Report**.

Roll back procedure

To roll back to previous version of Opswat SDK:

1. Navigate to **“Manage Endpoint Security Assessment PlugIn Versions”** section on **Authentication > Endpoint Security > Host Checker** page.
2. Uncheck **Enable migration of Opswat SDK from old to new version (V3 to V4)**.
3. Enable **Activate Older Opswat SDK in ESAP for Host Checker** policy evaluation.

4. Click **Save ESAP changes**.

☐ Enable migration of Opswat SDK from old to new version (V3 to V4)

Note: Enabling this option starts Opswat SDK V3 to V4 migration on the client machines. This option enforces V3 Opswat SDK usage in host checker policy definitions by enabling Older SDK usage option below, so that host check happens properly irrespective of whether client machine has Opswat V3 or V4 SDK installed. During the next host check on the client machine, Opswat V4 SDK will be installed. Minimum ESAP version "3.4.2" is needed for successful migration.

☒ **Activate Older Opswat SDK in ESAP for Host checker policy evaluation.**

Note: ESAP contains two versions of Opswat SDKs for supporting policy evaluation. It is recommended to use the newer version of the Opswat SDK. Use the older version if you have Pulse Clients before 5.2R5, Pulse Connected Secure appliances before 8.2R5, or Pulse Policy Secure appliances before C5.3R5.

☐ Enable Active ESAP package on the client

Note: Enabling this option ensures that the active ESAP package is used on all the client machines. If the client machine contains a newer ESAP package it will be replaced with the active ESAP version.

Package: No file chosen ☐ Set as active after upload

End User Flow

User logging in from browser or User logging in from Ivanti Secure Access Client for L3 connection

- Client machine has Opswat V3 SDK installed.
- Host Check starts on the client machine as part of connection establishment.
- Server sends the required information to client for upgrading V3 to V4 SDK.
- Client downloads V4 SDK and collects the installed security products details using newly installed V4 SDK and sends the detected product details to server.

- Server evaluates configured Opswat based rules by consuming the details received from client machine.
- Host Checker continues to use the installed V4 SDK on client machine for subsequent host checks and connections.

User logging in from Ivanti Secure Access Client for L2 connections

- Client machine has Opswat V3 SDK installed.
- Host Check starts on the client machine as part of connection establishment.
- Server sends the required information to client for upgrading V3 to V4 SDK.
- During L2 connection, client fails to download V4 SDK.
- Host Checker collects the installed security products details using existing V3 SDK and sends the detected product details to server.
- Server evaluates configured Opswat based rules by consuming the details received from client machine.
- L2 connection is established followed with an L3 connection.
- Server detects L2 followed by L3 connection attempt and remembers that ESAP upgrade is needed on the client machine.
- Host Check is triggered again on client machine during L3 connection.
- Server sends the required information to client for upgrading V3 to V4 SDK.
- Client downloads V4 SDK (because L2 connection is complete already) and collects the installed security products details using newly installed V4 SDK and sends the detected product details to server.
- Server evaluates configured Opswat based rules by consuming the details received from client machine.
- Host Checker continues to use the installed V4 SDK on client machine for subsequent host checks and connections.

Host checking is done twice for the same client machine (once during L2 connection and once during L3 connection) for the first time. However, Host Checking is done only once for the subsequent connections as the client machines has the Opswat V4 SDK installed.

Activating the Opswat SDK Version

Beginning with Release 5.3R5, IPS supports both v3 and v4 SDKs provided by OPSWAT. The default SDK version used is v4, but it can be reconfigured based on your requirement. The product/vendor names used by v3 and v4 SDK might differ. Due to the product/vendor names mismatch, there is a possibility that the rules become empty while creating Host Checker rule with v3 SDK activated and upon enabling v4 SDK. To avoid this, a migration page is added to help the administrators in migrating the policies from v3 to v4 SDK.

To use v3 or v4 SDK:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Enable the **Activate Older SDK in ESAP for Host Checker policy evaluation** check box for v3 SDK.

3. Disable the **Activate Older SDK in ESAP for Host Checker policy evaluation** check box for v4 SDK.

☐ Set as active after upload

Save ESAP Changes

* indicates required field

It is recommended to disable this option for using newer version of OPSWAT SDK, after all the Ivanti Secure Access Client are upgraded.

Click **Save ESAP Changes**. A confirm Activation page appears which lists the products and/or vendors, which are no longer supported in that particular ESAP SDK version. From the drop downlist, admin can select one or many new products /vendors instead of the existing product/vendor.

Confirm Activation

The current configuration contains the following list of products and/or vendors that are no longer supported in ESAP version '3.0.1'. These items will be automatically deleted from the corresponding Host Checker rules upon ESAP activation.

10 records per page Search:

Policy Name:	Platform:	Rule Name:	Rule Type:	Product/Vendor Name:	New Product/Vendor Name(s):
Hc_check	Mac	av	Specific Vendor	Kaspersky Labs	Kaspersky Lab
		firewall	Specific Vendor	Apple Computer, Inc.	
	Windows	antivirus	Specific Vendor	Microsoft Corp.	
		firewall	Specific Product	Microsoft Windows Firewall (10.x)	
		hd	Specific Product	Symantec Encryption Desktop (10.x)	
			Specific Vendor	Symantec Corp.	Nothing selected
		patch	Specific Product	System Center Configuration Manager (5.x)	Nothing selected

Showing 1 to 7 of 7 entries

← Previous 1 Next →

- Only the products/vendors, which get changed are listed. If some rules have some products/vendors whose names are not changed, those products/vendors will be automatically migrated and will not be listed.
- When the ESAP version is changed from upper version to lower version and if any product is not listed in the selected ESAP version, then the backup configuration will not work.

4. Enable **Backup 'User Configuration' and 'XML containing configured Host Checker, Realms and Roles details** check box to create a local backup of user configurations under **Maintenance > Archiving > Local Backups**.

evaluated as failed and may cause the host checker policy to fail. We strongly recommend that these empty HC rules be deleted manually after ESAP activation.

Policy Name:	Platform:	Rule Name:	Rule Type:
Hc_check	Mac	av	Specific Vendors
		firewall	Specific Vendors
	Windows	firewall	Specific Products
		hd	Specific Products
			Specific Vendors
		patch	Specific Products

☒ Backup 'User Configuration' and 'XML containing configured Host Checker, Realms and Roles details'

Note: A backup of User Configuration and XML containing Host Checker policies, Realms and Roles details will be created under 'Maintenance->Archiving->Local Backups'
This may take several minutes (depends on configuration of the server)

Please click on Confirm if you want to continue activation of ESAP, otherwise click on Cancel.

Server maintains a maximum of 5 backups. To capture a new backup, older backup will be automatically deleted.

5. Click **Confirm**.

Changing the Active ESAP Package

Administrator can activate any of the already uploaded ESAP packages by selecting the corresponding radio button under "Manage Endpoint Security Assessment Plugin Versions" table and then clicking on "Save ESAP Changes" button.

To change the active ESAP packages:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Under **Manage Endpoint Security Assessment Plugin Versions**, select the required ESAP version.
3. Click **Save ESAP Changes**.

▼ Manage Endpoint Security Assessment Plugin Versions

☒ Activate Older Opswat SDK in ESAP for Host checker policy evaluation.

Note: ESAP contains two versions of Opswat SDKs for supporting policy evaluation. It is recommended to use the newer version of the Opswat SDK. Use the older version if you have Pulse Clients before 5.2R5, Pulse Connect Secure appliances before 6.2R5, or Pulse Policy Secure appliances before CS.3R5.

☐ Enable Active ESAP package on the client

Note: Enabling this option ensures that the active ESAP package is used on all the client machines. If the client machine contains a newer ESAP package it will be replaced with the active ESAP version.

Package: No file chosen ☐ Set as active after upload

* indicates required field

If the client machine has newer ESAP package and if it has to be replaced, then select "Enable the Active ESAP package". See [Enabling the Active ESAP Package](#) to know about the procedure.

Enabling the Active ESAP Package

Administrator can enable “Enable Active ESAP package on the client” checkbox to ensure that client machine always uses the active ESAP package, even if the active ESAP package is older than the version installed on the client system. In case client machine has newer ESAP package installed, it will be replaced with the older Active ESAP version with this option enabled.

To enable the active ESAP package:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Under **Manage Endpoint Security Assessment Plugin Versions**, enable Enable Active ESAP package on the client checkbox.

▼ Manage Endpoint Security Assessment Plugin Versions

☒ Enable Active ESAP package on the client

Note: Enabling this option ensures that the active ESAP package is used on all the client machines. If the client machine contains a newer ESAP package it will be replaced with the active ESAP version.

Package: No file chosen ☐ Set as active after upload

3. Click **Save ESAP Changes**.

Updating Virus Signature Database

You can automatically import the current virus-signature version-monitoring from the Ivanti staging site at a specified interval, or you can download the files from Ivanti portal and use your own staging server. You can also configure a proxy server as a staging site between IPS and the Ivanti site. To use a proxy server, you enter the server network address, port, and authentication credentials, if applicable.

To access the Ivanti staging site for updates, you must enter the credentials for your Ivanti Support account.

For patch assessment remediation with Ivanti you can use OPSWAT (a third-party vendor) to automatically download patches from trusted sources to the endpoint.

To configure IPS to automatically import the current virus signature version-monitoring from the Ivanti staging site:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Select **Virus signature version monitoring**.
3. Select **Auto-update virus signatures list**.
4. For Download path, leave the existing URLs of the staging sites where the current lists are stored. The default URLs are the paths to the Ivanti staging site:
5. For Download interval, specify how often you want IPS to automatically import the current list(s).
6. For Username and Password, enter your Ivanti Global Support Center credentials.
7. Click **Save Changes**.

To manually import the current virus signature version-monitoring lists:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Click **Virus signature version monitoring**.
3. Download the list(s) from the Ivanti staging site to a network server or local drive on your computer by entering the Ivanti URLs in a browser window:
 - https://download.pulsesecure.net/software/av/uac/epupdate_hist.xml
 - <https://download.pulsesecure.net/software/hc/patchdata/patchupdate.dat>

4. Under **Manually import virus signatures** list, click **Browse**, select the list, and then click **OK**.
5. Click **Save Changes**.

If you use your own staging site for storing the current list(s), you must upload the trusted root certificate of the CA that signed the staging's server certificate to IPS.

To use a proxy server as the auto-update server:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Select **Virus signature version monitoring**.
3. Select **Auto-update virus signatures list**.
4. For Download path, leave the existing URLs of the staging sites where the current lists are stored. The default URLs are the paths to the Ivanti staging site:
 - https://download.pulsesecure.net/software/av/uac/epupdate_hist.xml
(for auto update virus signatures list)
 - <https://download.pulsesecure.net/software/hc/patchdata/patchupdate.dat>
(for auto update patch management)
5. For Download interval, specify how often you want IPS to automatically import the current lists.
6. For Username and Password, enter your Ivanti Global Support Center credentials.
7. Select the **Use Proxy Server** check box.
8. For IP Address, enter the IP address of your proxy server.
9. For Port, enter the port that the Ivanti Global Support Center will use to communicate with your proxy server.
10. If your proxy server is password protected, type the Username and Password of the proxy server.
11. Click **Save Changes**.

Understanding Host Checker Policy Remediation

This topic describes Host Checker policy remediation.

Remediation Options

You can specify general remediation actions for Host Checker to take if an endpoint does not meet the requirements of a policy. For example, you can display a remediation page to the user that contains specific instructions and links to resources to help the user bring their endpoint into compliance with Host Checker policy requirements.

You can also include a message to users (called a reason string) that is returned by Host Checker or an IMV and that explains why the client machine does not meet the Host Checker policy requirements.

For example, the user might see a remediation page that contains custom instructions, a link to resources, and reason strings:

For each Host Checker policy, you can configure two types of remediation actions:

- **User-driven**—Using custom instructions and reason strings, you can inform the user about the failed policy and how to make his computer conform. The user must take action to successfully re-evaluate the failed policy unless you configure an IMV to automatically remediate his computer. For instance, you can create a custom page that is linked to a policy server or Web page and enables the user to bring his computer into compliance.
- **Automatic (system-driven)**—You can configure Host Checker to automatically remediate the user's computer. For example, when the initial policy fails, you can kill processes, delete files, or allow automatic remediation by an antivirus rule, a firewall rule, or a registry setting rule. Host Checker does not inform users when performing automatic actions. (You could, however, include information in your custom instructions about the automatic actions.)

Remediation User Experience

Users might see a remediation page in the following situations:

- Before the user signs in:
 - If you enable custom instructions or reason strings for a policy that fails, the system displays the remediation page. The user has two choices:
 - Take the appropriate actions to make the endpoint conform to the policy and then click **Try Again** on the remediation page. Host Checker checks the user's computer again for compliance with the policy.
 - Leave the endpoint in its current state and click **Continue** to sign in. The user cannot access the realm, role, or resource that requires compliance with the failed policy.

If you do not configure the system with at least one realm that allows access without enforcing a Host Checker policy, the user must bring the endpoint into compliance before signing in.
 - If you do not enable custom instructions or reason strings for a policy that fails, Host Checker does not display the remediation page. Instead, a message displays telling the user that no additional information has been provided and to contact the system administrator. The system does not assign the user a role that allows access to protected resources.
- After the user signs in:
 - **Ivanti**—During a session, if a user's computer becomes noncompliant with the Host Checker policy, a message is displayed briefly in the system tray that informs the user of the noncompliance. The remediation page is displayed on the client.
 - **Agentless**—During a session, if a user's agentless computer becomes noncompliant with the Host Checker policy, the system displays the remediation page to inform the user of the noncompliance. On Windows agentless computers, Host Checker displays a bubble and tray icon if the endpoint becomes noncompliant. The user must click the bubble or tray icon to open a browser window that contains the remediation instructions. On Macintosh and Linux agentless computers, Host Checker automatically opens a browser window that contains the remediation instructions as soon as the endpoint is noncompliant.

Configuring Host Checker Policy

To configure a Host Checker policy:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Under Policies, click **New**.
3. Enter a name in the Policy Name field then click Continue. (Users see this name on the Host Checker remediation page if you enable custom instructions for this policy.)
4. Create one or more rules to associate with the policy.
5. Configure additional system-level options on **Authentication > Endpoint Security > Host Checker page**.
6. Determine the level at which you want to enforce Host Checker policies:
 - To enforce Host Checker policies when the user initially signs in, implement the policy at the realm level select **Users > User Realms > Select Realm > Authentication Policy > Host Checker**.
 - To allow or deny users access to specific roles based on compliance with Host Checker policies, implement the policies at the role level by using the **Users > User Roles > Select Role > General > Restrictions > Host Checker** page of the admin console.
 - To map users to roles based on their compliance with Host Checker policies, select Users > User Realms > Select Realm > Role Mapping and use custom expressions.
7. To create client-side logs. Select **System > Log/Monitoring > Client Logs/Settings and enable Host Checker** and **Ivanti secure Client** option.
8. If more than one valid session exists from the same system, and Host Checker is used in those sessions, all valid sessions are terminated if a user signs out from any of the sessions. To prevent this, turn off Host Checker for those sessions that do not need Host Checker.

Enable **Agentless Mode with Profiler** for using Agentless Host Checker policy evaluation. As a pre-requisite the Admin must configure the Profiler server to collect the endpoint attributes. Note that the Agentless Mode with Profiler functionality is also supported on the MAC Authentication Realm. Refer the Profiler documentation for configuration and other details.

Configuring Antivirus Rule with Remediation Options

Use this rule type to configure antivirus rule along with remediation actions. You can also monitor policies to ensure that logged-in endpoints maintain compliance status, and remediate the endpoint to another role or realm depending on the current status.

To configure a predefined antivirus rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a policy or click on existing policy in the Policies section of the page.
3. Select the tab for Windows or Mac, depending on the platform for which this rule is intended.
4. Under Rule Settings, select **Predefined: Antivirus** and click **Add**.

Endpoint Security > Host Checker > HC > Windows > Add Predefined Rule : Antivirus

Add Predefined Rule : Antivirus

Rule Type: Antivirus

*Rule Name:

▼ Criteria

☐ Require any supported product.

☒ Require specific products/vendors

☐ Require any supported product from a specific vendor.

☐ Require specific products

▼ Optional

The following check is supported by these Antivirus products. For any other products, this check will be ignored.

☐ Successful System Scan must have been performed in the last: days.

The following check is supported by these Antivirus products. For any other products, this check will be ignored. For this check to be effective, enable the 'Auto-update virus signatures list' option or manually import the virus signatures list on Endpoint Security page.

☒ Check for the Virus Definition files

☒ Virus Definition files should not be older than: Updates.

Note: The value of updates should be in the range of 1-20

☐ Virus Definition files should not be older than: Days.

Note: The value of days should be in the range of 1-30. Minimum version required on the client machine to support the number of days check is 5.4 for OAC and 3.0 for Pulse. For agentless HC the client version does not matter.

☒ Enable Custom Message Per Rule

☐ Monitor this rule for change in result

Note: Enabling this option will report change in compliance for this rule to the Ivanti Policy Secure immediately. The client component requires additional computing cycles to report change in compliance immediately. We strongly recommend that this option be enabled for rules that are dynamic in nature, for example a rule for RTP check provided by AntiVirus software. For other rules the host checker update frequency should be used to get periodic health checks from endpoints.

5. Enter the name of the antivirus rule.

6. To determine if your software vendor's product is supported for the System Scan check, click **these Antivirus products**. A new window opens with a list of the products that support the feature.
7. Select or clear the check box next to **Successful System Scan must have been performed in the last _ days**, and enter the number of days in the box. If you select this check box, a new option is displayed. If the remediation action to start an antivirus scan successfully begun, you can override the previous check.
8. Select or clear **Consider this rule as passed if 'Full System Scan' was started successfully as remediation** check box.
9. Select or clear the **Check for Virus Definition files** check box. If you select this check box, then choose either **Virus Definition files should not be older than n Updates** (the range for this value is 1 - 20) or **Virus Definition files should not be older than n Days** (the range for this value is 1 - 30).
10. Select one of the following options:
 - **Require any supported product** allows you to check for any product (rather than requiring you to select every product separately). This option button reveals a list of products in the remediation section to allow you to enable remediation options which are product specific.
 - **Require specific products/vendors** allows you to define compliance by allowing any product by a specific vendor or provides functionality that allows you to select individual products to define compliance.

After you select your vendors and products, remediation options appear on the page.

For each of the following remediation actions:

- **Download latest virus definition files**—Obtains the latest available file for the specified vendor from the vendor's website.
- **Turn on Real Time Protection**—Launches the virus-scanning mechanism for the specified vendor.
- **Start Antivirus Scan**—Performs a real-time virus scan for the specified vendor.

The check box is active if the action is supported for your product.

If your antivirus product is not supported, you can click the remediation column headers to determine what vendors and products are supported.

- If your product is supported, select the check box for the remediation action that you want to apply.
- Under Optional, select **Monitor this rule for change** in result to continuously monitor the policy compliance of endpoints. If this check box is selected, the compliance status of an endpoint that has successfully logged in changes, IPS initiates a new handshake to reevaluate realm or role assignments
- (Optional) Select Enable Custom Instructions, to provide detailed instructions or description in the form of HTML or plain text.
- Click **Save Changes** to save the antivirus rule and enforce antivirus remediation.
- (Optional) Add more rules to the policy, specify how Host Checker should evaluate multiple rules within the policy, and define remediation options.

Configuring Firewall Rule with Remediation Options

Use this rule type to create a Host Checker firewall rule that requires the endpoint to have a specific firewall installed and running before it connects to the network.

To configure a Host Checker predefined firewall rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a policy or click an existing policy in the Policies section of the page.
3. Select the tab for Windows or Mac, depending on the platform for which this rule is intended.

4. Under Rule Settings, select **Predefined: Firewall** and click **Add**.

The screenshot shows a configuration window titled "Add Predefined Rule: Firewall". It includes a "Rule Type: Firewall" label and a "Rule Name" input field. Under the "Criteria" section, there are four radio button options: "Require any supported product", "Require specific products/vendors" (which is selected), "Require any supported product from a specific vendor", and "Require specific products". The "Optional" section contains a checked checkbox for "Enable Custom Message Per Rule" and a large text area for a custom message, with a note "HTML is allowed" to its right. At the bottom, there is an unchecked checkbox for "Monitor this rule for change in result" and a detailed note explaining that enabling this option reports compliance changes immediately to the Ivanti Policy Secure client, which then reports to the host checker.

5. Enter a name for the firewall rule.
6. Select one of the following options:
- **Require any supported product** allows you to check for any product (rather than requiring you to select every product separately). This option button provides a list of products in the remediation section to allow you to enable remediation options which are product specific.
 - **Require specific products/vendors** allows you to define compliance by allowing any product by a specific vendor or provides functionality that allows you to select individual products to define compliance.
7. After you select your vendors and products, remediation options appear on the page.
8. If your firewall is supported, select the **Turn on Firewall** check box.
9. Under Optional, select **Monitor this rule for change** in result to continuously monitor the policy compliance of endpoints. If this check box is selected, and a change in compliance status on an endpoint that has successfully logged in occurs, IPS initiates a new handshake to reevaluate realm or role assignments.
10. (Optional) Select Enable Custom Instructions, to provide detailed instructions or description in the form of HTML or plaint text.
11. Click **Save Changes** to save the firewall rule and enforce firewall remediation.

12. (Optional) Add more rules to the policy, specify how Host Checker should evaluate multiple rules within the policy, and define remediation options.

Configuring Malware Rule

Use this rule type to check for installed malware on endpoints.

To configure a Host Checker Predefined malware rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new or click an existing policy in the Policies section of the page.
3. Select the tab for Windows.
4. Under Rule Settings, select **Predefined: Malware** and **click Add**.

The screenshot shows the 'Add Predefined Rule: Malware' configuration window. At the top, the breadcrumb is 'Configuration > Host Checker Policy > Add Predefined Rule: Malware'. Below this, the title is 'Add Predefined Rule: Malware'. The 'Rule Type' is set to 'Malware'. There is a required field for '*Rule Name'. Under the 'Criteria' section, there are two lists: 'Available Types' and 'Selected Types'. The 'Available Types' list includes 'InfoExpress CyberGatekeeper Agent', 'Sygate Enforcement API', and 'Sygate Security Agent'. There are 'Add ->' and '<- Remove' buttons between the lists. The 'Selected Types' list is currently empty. Below the lists, there is an 'Optional' section with a checkbox for 'Monitor this rule for change in result'. A note explains that enabling this option will report change in compliance immediately, but the client component requires additional computing cycles. At the bottom, there are 'Save Changes' and 'Cancel' buttons. A footnote indicates that an asterisk (*) denotes a required field.

Configuration > Host Checker Policy > Add Predefined Rule: Malware

Add Predefined Rule: Malware

Rule Type: Malware

*Rule Name:

▼ Criteria

Available Types: Selected Types:

InfoExpress CyberGatekeeper Agent Add ->

Sygate Enforcement API <- Remove

Sygate Security Agent

▼ Optional

☐ Monitor this rule for change in result

Note: Enabling this option will report change in compliance for this rule to the Pulse Policy Secure immediately. The client component requires additional computing cycles to report change in compliance immediately. We strongly recommend that this option be enabled for rules that are dynamic in nature, for example a rule for RTP check provided by Avast software. For other rules the host checker update frequency should be used to get periodic health checks from endpoints.

Save Changes Cancel

* indicates required field

5. From the Criteria, select the **Malware Software** to be installed on the endpoint.
6. Click **Save Changes**.

Configuring AntiSpyware Rule

Use this rule type to check for installed antispyware on endpoints.

To configure a Host Checker Predefined Spyware rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new or click an existing policy in the Policies section of the page.
3. Select the tab for Windows or Mac, depending on the platform for which this rule is intended.
4. Under Rule Settings, select **Predefined: AntiSpyware** and **click Add**.

The screenshot shows the 'Add Predefined Rule : AntiSpyware' configuration window. It includes a 'Rule Type' dropdown set to 'AntiSpyware' and a 'Rule Name' text box. Under the 'Criteria' section, there is a note about Anti-Virus products and three radio button options: 'Require any supported product', 'Require specific products/vendors' (which is selected), 'Require any supported product from a specific vendor', and 'Require specific products'. The 'Optional' section has a checked checkbox for 'Enable Custom Message Per Rule' and a large text area for a custom message, with a note that 'HTML is allowed'. At the bottom, there is an unchecked checkbox for 'Monitor this rule for change in result' and a detailed note about enabling this option for dynamic rules like RTP checks.

5. Enter a name for the firewall rule.

6. Select one of the following options:
 - **Require any supported product** allows you to check for any product (rather than requiring you to select every product separately). This option button provides a list of products in the remediation section to allow you to enable remediation options which are product specific.
 - **Require specific products/vendors** allows you to define compliance by allowing any product by a specific vendor or provides functionality that allows you to select individual products to define compliance.
7. Under Optional, select **Monitor this rule for change in result** to continuously monitor the policy compliance of endpoints. If this check box is selected, and a change in compliance status on an endpoint that has successfully logged in occurs, IPS initiates a new handshake to re-evaluate realm or role assignments.
8. (Optional) Select Enable Custom Instructions, to provide detailed instructions or description in the form of HTML or plaint text.
9. Click **Save Changes**.
10. (Optional) Add more rules to the policy, specify how Host Checker should evaluate multiple rules within the policy, and define remediation options.

Configuring Hard Disk Encryption Rule

Use this rule type to check for installed Hard Disk Encryption software on endpoints and specify the drives which needs to be encrypted.

To configure a predefined hard disk encryption rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.
3. Select the tab for Windows or Mac, depending on the platform for which this rule is intended.

4. Under Rule Settings, select **Predefined: HardDisk Encryption** and click **Add**.

rule (Predefined Rule : HardDisk Encryption)

Rule Type: HardDisk Encryption

*Rule Name:

♥ *Criteria

☒ Require any supported product.

☐ Require specific products/vendors

Drive Configuration Details:

☐ All Drives

☒ Specific Drives

Drive Letters: Example: To check encryption status of C, D and E drives, configure "C,D,E"

☐ Consider policy as passed if the drives are not detected.

Note: Enabling this option will result in policy pass if any of the configured drives are not detected on the endpoint machine.

☒ Consider policy as passed if the drive Encryption is in progress.

Note: Enabling this option will result in policy pass if any of the configured drives are not fully encrypted, but the encryption process is in progress on the endpoint machine.

Powered by
OPSWAT

* indicates required field

6. Enter a Rule Name for the HardDisk Encryption rule.

7. Select one of the following options:

- **Require any supported product** allows you to check for any product (rather than requiring you to select every product separately). This option button provides a list of products in the remediation section to allow you to enable remediation options which are product specific.
- **Require specific products/vendors** allows you to define compliance by allowing any product by a specific vendor or provides functionality that allows you to select individual products to define compliance.

8. Under Drive Configuration, select the required option.

- **All Drives--(Default)** Select this option to check if all the drives on the client machine are encrypted.
- **Specific Drives**-Select this option to check if only specific drives on the client machine are encrypted.
 - **Drive Letters**– Enter the drive name. For example, C, D, E.
 - **Consider policy as passed if the drives are not detected**– Select this option to consider policy as passed if the drives are not detected
 - **Consider policy as passed if the drive Encryption is in progress**– Select this option to allow the Host Checker policy to pass if the encryption process is in progress and the drive is not fully encrypted. The drive encryption process takes time to complete depending up on the drive size and contents. For multiple drives, the HC policy passes only if the encryption process is in progress in all the drives.

9. Click **Save Changes**.

Configuring Common Vulnerability and Exposure (CVE) Check Rules

Host Checker is used for analyzing the health of the endpoint before providing access to the network. As endpoints are vulnerable to many types of new attacks such as Ransomware attack. It becomes extremely important to identify such endpoints, which are vulnerable to any attacks. The CVE lists some of these attacks along with the required software patches to prevent from such attacks. IPS provides the CVE check rule, which helps in identifying the endpoints which are vulnerable using the OPSWAT library. If the endpoint is vulnerable appropriate action is taken based on the rule configuration. For example, the user can be denied from accessing the network.

-
- CVE check rule is supported from ESAP 3.2.3 onwards.
 -  - OPSWAT version 3 does not support CVE rules. These rules will always be evaluated as failed and may cause the host checker policy to fail. It is recommended to delete CVE rules if you are using OPSWAT V3 SDK for evaluation.
-

To configure a predefined CVE check rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.

- 3. Click the **Windows** tab.
- 4. Under Rule Settings, select **Predefined: CVE Checks** and click **Add**.

Configuring Patch Management Rules

You can configure Host Checker to check for installed Patch Management Software on endpoints.

Patch management software detects patch status based on the configured rules on corresponding patch management server. Detection of patches status on the client machine depends on the support provided by the 3rd party patch management solution that is used. Hence different patch management software on the same client can report the status differently. To avoid conflicts, administrator is allowed to configure only one patch management software product on policy configuration page.

It provides options to configure various Severity and Category options that administrator is interested in. These additional details are used during policy evaluation such that only the missing patches that belongs to configured "Severity" and "Category" are considered. Any other patches that does not belong to configured "Severity" and "Category" are not considered during policy evaluation.

The default "Severity" options selected in policy are Critical, Important. The default "Category" options selected in policy are Security Update, Critical Update, Regular Update, Driver Update.

- The remediation support for patch management rule is available only for Windows platform using SCCM client.
 - Patch Management on Mac is not supported with OPSWAT SDK V3 and Ivanti Secure Access Client.
-

To configure a predefined patch management rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.
3. Click the **Windows/Mac** tab.

4. Enter a Rule Name for the Patch Management rule.

Configuring OS Checks Rule

You can configure Host Checker to check for the Windows/MAC operating systems and minimum service pack versions that you specify. Any service pack whose version is greater than or equal to the version you specify satisfies the policy.

i OS Check rule is supported starting from MAC OS X El Captain (10.11) and above.

To configure a rule for OS checks:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.

3. Click the **Windows/Mac** tab.
4. Enter a Rule Name for the OS checks rule.

5. Under Rule Settings, select **Predefined: OS checks** and click **Add**.

Configuring Third-Party NHC Rule

Use this rule type to specify the location of a custom DLL. Host Checker calls the DLL to perform customized client-side checks.

To configure a rule for third-party NHC:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Under Rule Settings, select **Custom: 3rd Party NHC Check** and then click **Add**.

Configuration > Host Checker Policy > Add Custom Rule: 3rd Party NHC Check

Add Custom Rule: 3rd Party NHC Check

Rule Type: 3rd Party NHC Check

*Rule Name:

▼ *Criteria

*Vendor Name:

*Path to NHC DLL:

▼ Optional

☐ Monitor this rule for change in result

Note: Enabling this option will report change in compliance for this rule to the Pulse Policy Secure immediately. The client component requires additional computing cycles to report change in compliance immediately. We strongly recommend that this option be enabled for rules that are dynamic in nature, for example a rule for RTP check provided by AntiVirus software. For other rules the host checker update frequency should be used to get periodic health checks from endpoints.

* indicates required field

3. Enter a name for the NHC Check rule.
4. Under Criteria, enter the Vendor name and Path to NHC DLL.
5. Under Optional, select **Monitor this rule for change in result** to continuously monitor the policy compliance of endpoints. If this check box is selected, and a change in compliance status on an endpoint that has successfully logged in occurs, the IPS initiates a new handshake to re-evaluate realm or role assignments.
6. Click **Save Changes**.

Configuring Ports Rule

Use this rule type to control the network connections that a client can generate during a session. This rule type ensures that certain ports are open or closed on the client machine before the user can access the system.

To configure a custom port rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.
3. Under Rule Settings, select **Custom: ports** and then click **Add**.

Configuration > Host Checker Policy > Add Custom Rule : Ports

Add Custom Rule : Ports

Rule Type: Ports

*Rule Name:

▼ *Criteria

*Port List: Enter port numbers seperated by comma

☐ Required ☒ Deny

▼ Optional

☐ Monitor this rule for change in result

Note: Enabling this option will report change in compliance for this rule to the Pulse Policy Secure immediately. The client component requires additional computing cycles to report change in compliance immediately. We strongly recommend that this option be enabled for rules that are dynamic in nature, for example a rule for RTP check provided by AntiVirus software. For other rules the host checker update frequency should be used to get periodic health checks from endpoints.

* indicates required field

4. Enter a name for the port rule.
5. Under Criteria, enter a comma delimited list (without spaces) of ports or port ranges, such as: 1234,11000- 11999,1235. Select Required if you want these ports to be open on the client machine or Deny if you want them to be closed.
6. (Windows only) Under Optional, select Monitor this rule for change in result to continuously monitor the policy compliance of endpoints. If this check box is selected, and a change in compliance status on an endpoint that has successfully logged in occurs, the IPS initiates a new handshake to re-evaluate realm or role assignments.
7. Click **Save changes**.

Configuring Process Rule

Use this rule type to control the software that a client may run during a session. This rule type ensures that certain processes are running or not running on the client machine before the user can access protected resources.

To configure a custom process rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.
3. Under Rule Settings, select Custom: **Process** and then click **Add**.

Configuration > Host Checker Policy > Add Custom Rule : Process

Add Custom Rule : Process

Rule Type: Process

*Rule Name:

▼ *Criteria

*Process Name:

☐ Required ☒ Deny

▼ Optional

MD5 Checksums: One MD5 checksum per line.

SHA256 Checksums: One SHA256 checksum per line.

☐ Monitor this rule for change in result

Note: Enabling this option will report change in compliance for this rule to the Pulse Policy Secure immediately. The client component requires additional computing cycles to report change nature , for example a rule for RTP check provided by AntiVirus software. For other rules the host checker update frequency should be used to get periodic health checks from endpoints.

* indicates required field

4. Enter a name for the process rule.

5. Under Criteria, enter the name of a process (executable file), such as: good-app.exe. You can use a wildcard character to specify the process name. For example: good*.exe. Select Required to require that this process is running or Deny to require that this process is not running.
6. Under Optional, enable the checks required from the following:
 - Specify the MD5 checksum value of each executable file to which you want the policy to apply. For example, an executable may have different MD5 checksum values on a desktop, laptop, or different operating systems. On a system with OpenSSL installed—Macintosh and Linux systems have OpenSSL installed by default—you can determine the MD5 checksum by using this command: `openssl md5 <processFilePath>`.
 - Specify the SHA256 checksum value of each file.
 - Select or clear the check box next to Monitor this rule for change in result. With the checkbox enabled, it continuously monitors the policy compliance of endpoints. If this check box is selected, and a change in compliance status on an endpoint that has successfully logged in occurs, the IPS initiates a new handshake to re-evaluate realm or role assignments.
7. Click **Save Changes**.

Configuring File Rule

Use this rule type to ensure that certain files are present or not present on the client machine before the user can access. You may also use file checks to evaluate the age and content (through MD5 checksums) of required files and allow or deny access accordingly.

To configure a custom file rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.
3. Under Rule Settings, select **Custom: File** and then click **Add**.
4. Enter a name for the file rule.

Configuration > Host Checker Policy > Add Custom Rule : File

Add Custom Rule : File

Rule Type: File

*Rule Name:

▼ *Criteria

*File Name: Example: c:\temp\bad-file.txt or <%windir%>\bad-file.txt

☐ Required ☒ Deny

▼ Optional

Minimum version:

File modified less than: days ago.

MD5 Checksums: One MD5 checksum per line.

SHA256 Checksums: One SHA256 checksum per line.

☐ Monitor this rule for change in result

Note: Enabling this option will report change in compliance for this rule to the Pulse Policy Secure immediately. The client component requires additional computing cycles to report change nature , for example a rule for RTP check provided by AntiVirus software. For other rules the host checker update frequency should be used to get periodic health checks from endpoints.

* indicates required field

5. Under Criteria, enter the name of a file (any file type), For example, **c:\temp\bad-file.txt or /temp/bad-file.txt**. You can use a wildcard character to specify the file name. For example: *.txt. You can also use an environment variable to specify the directory path to the file. (You cannot use a wildcard character in the directory path.) Enclose the variable between the <% and %> characters. For example: **<%windir%>\bad-file.txt**
6. Select Required to require that this file is present on the client machine or Deny to require that this file is not present.

7. (Windows only) Under Optional, enable the checks required from the following:
 - Specify the minimum version of the file (optional). For example, if you require notepad.exe to be present on the client, you can enter 5.0 in the field. Host Checker accepts version 5.0 and above, of notepad.exe.
 - Specify the maximum age (File modified less than n days) (in days) for a file (optional). If the file is older than the specified number of days, then the client does not meet the attribute check requirement.
 - Specify the MD5 checksum value of each file to which you want the policy to apply (optional). On Macintosh and Linux you can determine the MD5 checksum by using this command: **openssl md5 <filePath>**
8. Specify the SHA256 checksum value of each file.
9. Select Monitor this rule for change in result to continuously monitor the policy compliance of endpoints. If this check box is selected, and a change in compliance status on an endpoint that has successfully logged in occurs, the IPS initiates a new handshake to re-evaluate realm or role assignments.
10. Click **Save Changes**.

Configuring Registry Settings Rule

Use this rule type to control the corporate PC images, system configurations, and software settings that a client must have to access the IPS. This rule type ensures that certain registry keys are set on the client machine before the user can access the IPS. You may also use registry checks to evaluate the age of required files and to allow or deny access accordingly.

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.

- Under Rule Settings, select **Custom: Registry Setting** and then click **Add**.

Configuration > Host Checker Policy > Add Custom Rule : Registry Setting

Add Custom Rule : Registry Setting

Rule Type: Registry Setting

*Rule Name:

▼ *Criteria

Registry Root key: HKEY_LOCAL_MACHINE ▼

Registry Subkey:

Name:

Type: String ▼

Value:

☐ Check for 64-bit registry

Note: Check for 64 bit registry. This option is applicable only for 64-bit versions of Windows. By default, Host Checker checks only 32-bit registry.

☐ Minimum version

▼ Optional

☐ Monitor this rule for change in result

Note: Enabling this option will report change in compliance for this rule to the Pulse Policy Secure immediately. The client component requires additional computing cycles to report change in compliance immediately. We strongly recommend that this option be enabled for rules that are dynamic in nature, for example a rule for RTP check provided by AntiVirus software. For other rules the host checker update frequency should be used to get periodic health checks from endpoints.

▼ Remediation

☐ Set Registry value specified in criteria

- Enter a name for the registry setting rule.

5. Under the criteria:

- Select a root key from the drop-down list.
- Enter the path to the application folder for the registry subkey.
- Enter the name of the key's value that you want to require. This name appears in the **Name** column of the Registry Editor.
- Select the key value's type (**String, Binary, or DWORD**) from the drop-down list (optional). This type appears in the Type column of the Registry Editor.
- Specify the required registry key value (optional). This information appears in the Data column of the Registry Editor.
- If the key value represents an application version, select **Minimum version** to allow the specified version or newer.

6. Under Optional, select **Monitor this rule for change in result to continuously monitor the policy compliance of endpoints**. If this check box is selected, and a change in compliance status on an endpoint that has successfully logged in occurs, the system initiates a new handshake to re-evaluate realm or role assignments.

7. Under Remediation, Select the check box for **Set Registry value** specified in criteria.

8. Click **Save Changes**.

Configuring NetBIOS Rule

Use this rule type to check the NetBIOS name of the client machine before the user can access IPS.

A maximum of 1,000 regex patterns are supported in a single NetBIOS rule. In case, if there are more than 1,000 regex patterns in a single rule, split the rule into multiple rules.

To configure a custom NetBIOS rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.
3. Under Rule Settings, select **Custom: File** and then click **Add**.

4. Enter a name for the NetBIOS rule.

Configuration > Host Checker Policy > Add Custom Rule : NetBIOS

Add Custom Rule : NetBIOS

Rule Type: NetBIOS

*Rule Name:

▼ *Criteria

*NetBIOS Names: One per line
Example: WINDOWS-PC,WIN*-PC,*-PC,WINDOWS*

☒ Required ☐ Deny

* indicates required field

Configuration > Host Checker Policy > Add Custom Rule : NetBIOS

Add Custom Rule : NetBIOS

Rule Type: NetBIOS

*Rule Name:

♥ *Criteria

*NetBIOS Names: One per line
Example: MACBOOK-PRO,MAC*-PRO,*-PRO,MACBOOK*

☒ Required ☐ Deny

Save Changes **Cancel**

* indicates required field

- Under Criteria, enter a comma-delimited list (without spaces) of NetBIOS names. The name can be up to 15 characters in length. You can use wildcard characters in the name and it is not case-sensitive. For example, md*, m*xp and *xp all match MDXP. Select Required to require that this file is present on the client machine or Deny to require that this file is not present.

For Mac OS, you can enter special characters "[!\"#\$%&'()*+,-./:;<=>?@\\[\]^_`{|}~]" and space is allowed between NetBIOS names.

- Select Required to require that NETBIOS name of the client machine match one of the names you specify, or Deny to require that the name does not match any name.
- Click **Save Changes**.

Configuring MAC Address Rule

Use this rule type to check the MAC addresses of the client machine before the user can access the IPS.

To configure a custom MAC Address Rule:

- Select **Authentication > Endpoint Security > Host Checker**.
- Create a new policy or click an existing policy in the Policies section of the page.

3. Under Rule Settings, select **Custom: MAC Address** and then click **Add**.
4. Enter a name for the MAC address rule.

Configuration > Host Checker Policy > Add Custom Rule : MAC Address

Add Custom Rule : MAC Address

Rule Type: MAC Address

*Rule Name:

♥ *Criteria

*MAC Addresses: Example
 00:11:85:bb:8c:*
 00:ff:***
 One per line

☒ Required ☐ Deny

Save Changes **Cancel**

* indicates required field

5. Under Criteria, enter a comma-delimited list (without spaces) of MAC addresses in the form XX:XX:XX:XX:XX:XX where the X's are hexadecimal numbers. For example: 00:0e:1b:04:40:29. You can use a * wildcard character to represent a two-character section of the address. For example, you can use a * to represent the "04", "40", and "29" sections of the previous example address: 00:0e:1b:*:* But you cannot use a * to represent a single character. For example, the * in the following address is not allowed: 00:0e:1b:04:40:*9
6. Select Required to require that a MAC address of the client machine matches any of the addresses you specify, or Deny to require that the all addresses do not match. A client machine will have at least one MAC address for each network connection, such as Ethernet, wireless, and VPN.
7. This rule's requirement is met if there is a match between any of the addresses you specify and any MAC address on the client machine.
8. Click **Save Changes**.

Configuring Machine Certificate Rule

Use this rule type to check that the client machine is permitted access by validating the machine certificate stored on the client machine.

To configure a machine certificate rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.
3. Under Rule Settings, select **Custom: Machine certificate** and then click **Add**.
4. Enter a name for the machine certificate rule.

Endpoint Security > Host Checker > DemoPolicy > Windows > Add Custom Rule: Machine Certificate

Add Custom Rule: Machine Certificate

Rule Type: Machine Certificate

*Rule Name:

▼ *Criteria

Select Issuer Certificate: Any Certificate ▼

▼ Optional

You can optionally require specific values in the machine certificate:

Certificate field (example "cn")	Expected value	
<input type="text"/>	<input type="text"/>	<input type="button" value="Add"/>
<input type="text"/>	<input type="text"/>	

☐ Consider policy as passed even if certificate expired but not for other cases (like invalid/missing/revoked etc)

Note: Enabling this option will result in policy pass even if user certificate is expired and use this option to allow users to renew certificate

* indicates required field

5. Under Criteria, Select Issuer Certificate list, select the certificate that you want to retrieve from the user's machine and validate. Or, select **Any Certificate** to skip the issuer check and only validate the machine certificate based on the optional criteria that you specify below.
6. (Optional) Select the Consider policy as passed even if certificate expired but not for other cases (like invalid/missing/revoked etc) to make host checker policy pass even if the user certificate is expired. Using this option the Admin can assign endpoints to have remediation roles, so that users can renew certificate with remediation roles. This option is disabled by default.
7. From the Optional fields (**Certificate field and Expected value**), specify any additional criteria that Host Checker should use when verifying the machine certificate.

- If more than one certificate is installed on the client machine that matches the specified criteria, The Host Checker client passes the first certificate it finds to IPS for validation.
- Admin must perform some additional configurations on the Client machine for installing machine certificate on MAC OS due to some restrictions from Apple. For more information, see [KB44148](#)

8. Click **Save Changes**.

Configuring Advanced Host Checking Rule

Use this rule type to combine multiple policies for performing advanced host checking. The supported policy types are ports, process, file, registry setting, NETBIOS, MAC address and machine certificate. It allows Administrator to dynamically configure the expected values from registry locations on the endpoint for evaluating the policies.

This feature is supported only on Windows platform.

To configure an advanced host checking rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new policy, or click an existing policy in the Policies section of the page.
3. Under Rule Settings, select **Custom: Advanced Host Checking** and then click **Add**.
4. Enter a name for the rule.

5. Select the check to be performed from the Rule Type list.

Configuration > Host Checker Policy > Add Custom Rule : Advanced Host Checking

Add Custom Rule : Advanced Host Checking

Rule Type: Advanced Host Checking

*Rule Name:

▼ *Criteria

*Select Check Type: Select the check to be performed

☐ Required ☒ Deny

*Method to obtain value: Registry Setting

Registry Root key:

Registry Subkey:

Name:

Type:

☐ Check for 64-bit registry

Note: Check for 64 bit registry. This option is applicable only for 64-bit versions of Windows. By default, Host Checker checks only 32-bit registry.

* indicates required field

6. Under Criteria, **Select Rule Type** list.

- Select Ports to check whether a specific port number is opened or closed on the endpoint.
 - Enable **Required/Deny** to check if the specified port is open/closed.
 - Select the registry root key- HKEY_LOCAL_MACHINE, HKEY_USERS, HKEY_CURRENT_USER, HKEY_CURRENT_CONFIG, or HKEY_CLASSES_ROOT.
 - Enter the registry subkey.
 - Enter the name of the registry.
 - Select the type of the registry- String, Binary, or DWORD.
 - Select **Check for 64-bit registry** to check the 64 bit registry on Windows. The default is 32 bit registry.

You can similarly add the check type for Process/File/NETBIOS/MAC Address. The port number/process name/file path/NETBIOS name/MAC address is obtained from the Registry setting.

Configuration > Host Checker Policy > Add Custom Rule : Advanced Host Checking

Add Custom Rule : Advanced Host Checking

Rule Type: Advanced Host Checking

*Rule Name:

▼ *Criteria

*Select Check Type: Select the check to be performed

☐ Required ☒ Deny

*Method to obtain Ports value

Registry Setting

Registry Root key:

Registry Subkey:

Name:

Type:

☐ Check for 64-bit registry

Note: Check for 64 bit registry. This option is applicable only for 64-bit versions of Windows. By default, Host Checker checks only 32-bit registry.

- Select **Registry Setting** to verify the specific registry values on the endpoint. You can define only the registry location in the policy and define another registry location, which provides the expected registry value.
 - Select the registry root key- HKEY_LOCAL_MACHINE, HKEY_USERS, HKEY_CURRENT_USER, HKEY_CURRENT_CONFIG, or HKEY_CLASSES_ROOT.
 - Enter the registry subkey.
 - Enter the name.
 - Select the type of the registry- String, Binary, or DWORD.
 - Configure another registry setting to fetch the expected registry value. Select the registry subkey, name, and type.

Configuration > Host Checker Policy > Add Custom Rule : Advanced Host Checking

Add Custom Rule : Advanced Host Checking

Rule Type: Advanced Host Checking

*Rule Name:

♥ *Criteria

*Select Check Type: Select the check to be performed

Registry Root key:

Registry Subkey:

Name:

Type:

☐ Check for 64-bit registry

Note: Check for 64 bit registry. This option is applicable only for 64-bit versions of Windows. By default, Host Checker checks only 32-bit registry.

*Method to obtain Registry Setting value

Registry Root key:

Registry Subkey:

Name:

Type:

☐ Check for 64-bit registry

Note: Check for 64 bit registry. This option is applicable only for 64-bit versions of Windows. By default, Host Checker checks only 32-bit registry.

- Select **Machine Certificate** to verify the required certificate is installed on the client machine certificate store.
- Select the issuer certificate from the list.

- Specify any additional criteria that Host Checker must use while verifying the certificate.
 - Enter the certificate field name. For example, cn.
 - Select the registry key.
 - Enter the registry subkey.
 - Enter the registry name.
 - Select the registry type.
 - Click **Add**.

Configuration > Host Checker Policy > Add Custom Rule : Advanced Host Checking

Add Custom Rule : Advanced Host Checking

Rule Type: Advanced Host Checking

*Rule Name:

▼ *Criteria

*Select Check Type: Select the check to be performed

*Select Issuer Certificate:

▼ Optional

You can optionally require specific values in the machine certificate:

Certificate field (example "cn")	Registry Key	Registry SubKey	Registry Name	Registry Type	Registry 64bit	
<input type="text"/>	<input type="text" value="HKEY_LOCAL_MACHINE"/>	<input type="text"/>	<input type="text"/>	<input type="text" value="String"/>	<input type="checkbox"/>	<input type="button" value="Add"/>

7. Click **Save Changes**.

Configuring System Integrity Protection Rule

System Integrity Protection (SIP) is a security feature introduced in Mac OS X El Capitan. This security feature from Apple provides security on the endpoint machine by restricting various actions that root user can perform on the client machine. System Integrity Protection is enabled by default but can be disabled.

IPS supports System Integrity Protection policy to check the status of System Integrity Protection (SIP) on the Mac OS endpoints. Using this, the administrators can provide different access level to the endpoints based on the status of "System Integrity Protection" on the client machines.

To configure a Host Checker Predefined SIP rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new or click an existing policy in the Policies section of the page.
3. Select the tab for **Mac**.
4. Under Rule Settings, select **Predefined: System Integrity Protection Rule** and click **Add**.

Configuration > Host Checker Policy > Add Predefined Rule : System Integrity Protection

Add Predefined Rule : System Integrity Protection

Rule Type: System Integrity Protection

*Rule Name:

♥ *Criteria

Ensure status of System Integrity Protection on client machine is in below state

☒ Enabled ☐ Disabled

Note: Status of System Integrity Protection on client machine is considered as disabled in case client machine (prior to El Capitan) does not have support for System Integrity Protection

* indicates required field

5. Enter the rule name.
6. Under Criteria, select **Enabled** to ensure that the System Integrity Protection on the client machine is enabled.
7. Click **Save Changes**.

Configuring Command Rule

Command Rule enables administrators to check the versions of the installed applications on the Mac OS endpoints.

To configure a Host Checker: Custom command rule:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create a new or click an existing policy in the Policies section of the page.
3. Select the tab for Mac.
4. Under Rule Settings, select **Custom: Command** and click **Add**.

Configuration > Host Checker Policy > Add Command

Add Command

Rule Type: Command

*Rule Name:

▼ *Criteria

* Command:

* Property list file: Note: Path of the Property list file on the client machine. Ex: /Applications/Utilities/Terminal.app/Contents/Info.plist

* Key in Property list file: Note: Key name in above Property list file. Ex: CFBundleShortVersionString

* Expected Value(s): Note: Multiple values can be provided by using comma as separator. Ex: 2000, 2001. Wildcard is supported in the expected value. Ex: 2*

* indicates required field

5. Enter the rule name.

6. Under Criteria, complete the following configuration:

- Select the command type as **default read (Read Settings)**.
- Specify the path of the property list file of the required application on the client machine.
- Enter the key name used in the property list file for obtaining the version of the application.
- Enter the expected version that needs to be present on the client machine.

7. Click **Save Changes**.

Ensure that the required ESAP package (which has support for Command Rule) is installed and activated on the server.

Using a Wildcard or Environment Variable in a Host Checker Rule

The following table lists the wildcards you can use to specify a file name in a File rule or a process name in a Process rule.

Wildcard Character	Description	Example
*	Matches any character	*.txt
?	Matches exactly one character	app-?.exe

In a **Custom File rule** for Windows, you can use the following environment variables to specify the directory path to a file:

Environment variable	Example Windows Value
<%APPDATA%>	C:\Documents and Settings\jdoe\Application Data
<%windir%>	C:\WINDOWS
<%ProgramFiles%>	C:\Program Files
<%CommonProgramFiles%>	C:\Program Files\Common Files
<%USERPROFILE%>	C:\Documents and Settings\jdoe

Environment variable	Example Windows Value
<%HOMEDRIVE%>	C:
<%Temp%>	C:\Documents and Settings \<username>\Local Settings\Temp

The following table lists File rules for Macintosh and Linux.

Environment variable	Example Macintosh Value
<%Java.home%>	/System/Library/Frameworks/JavaVM.framework/ Versions/1.4.2/Home
<%Java.io.tmpdir%>	/tmp
<%user.dir%>	/Users/admin
<%user.home%>	/Users/admin

Configuring Third-Party Integrity Measurement Verifiers (IMV)

The TNC standard enables the enforcement of security requirements for endpoints connecting to networks. You can configure Host Checker to monitor third-party TNC-compliant IMCs installed on client computers. To do so, you must:

1. Run the Third-party Integrity Measurement Verifier (IMV) Server installer on the system designated as the remote IMV server. Install the third-party IMVs and create the server certificates. You can download this installer from Maintenance > system > Installers.
2. Specify the remote IMV server so that IPS can communicate with it.
3. Implement the Host Checker policy. Once you configure the remote IMV server, IPS adds the policy type Custom: remote IMV.

Configuring a Remote IMV Server

The third-party IMVs are installed on the remote IMV server and not on IPS and then obtain a server certificate for the remote IMV server. Import the trusted root CA certificate of the CA that generated the server certificate to IPS. IPS then authenticates with the remote IMV server through the certificate. If you do not have a CA, install and use OpenSSL to generate a CA certificate.

To configure the remote IMV server:

1. Select **Maintenance > System > Installers** and download the third-party Measurement Verifier (IMV) server installer.
2. Run the installer on the system designated as the remote IMV server.
3. Install the third-party IMVs on the remote IMV server and the corresponding IMCs on the client systems.
4. Generate a server certificate from a certificate authority for the remote IMV server. The server's certificate Subject CN value must contain the actual host name or IP address of the remote IMV server.

The server certificate and the private key must be combined into a single PKCS#12 file and must be encrypted with a password. If you do not have a CA, you can use OpenSSL to create one, and then create a server certificate for the remote IMV server.

Configuring a Third-Party IMV Policy

To use Host Checker as a policy enforcement tool for managing endpoints, you must create global Host Checker policies at the system level and then implement the policies at the realm and role levels.

The Custom: Remote IMV option does not appear until you add the Remote IMV New Server and New IMV on the main Host Checker page.

To configure a third-party IMV policy:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Under Policies, click **New**.
3. Enter a name in the Policy Name field and click **Continue**. (Users see this name on the Host Checker remediation page if you enable custom instructions for this policy.)
4. Under Rule Settings, select Custom: Remote IMV and click **Add**.
5. In the Add Custom Rule: Remote IMV page:
 - In the **Rule Name** field, enter an identifier for the rule.
 - Under Criteria, select the **third-party IMV** to associate with this rule.

6. Click **Save Changes**.
7. Specify how Host Checker must evaluate multiple rules within the policy.
8. (Recommended) Specify remediation options for users whose computers do not meet the requirements specified in the policy.
9. Click **Save Changes**.
10. Implement the policy at the realm or role level.

Configuring General Host Checker Remediation

To specify remediation actions for a Host Checker policy:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Create or enable Host Checker policies.

3. Specify the remediation actions for Host Checker to perform if a computer does not meet the requirements of the current policy:

- **Enable Custom Instructions**—Enter the instructions to display to the user on the Host Checker remediation page. You can use the following HTML tags to format text and to add links to resources such as policy servers or web sites: `<i>`, ``, `
`, ``, and `<a href>`. For example:

You do not have the latest signature files.

`Click here to download the latest signature files.`

- **Kill Processes**—On each line, enter the name of one or more processes to kill if the computer does not meet the policy requirements. You can include an optional MD5 checksum for the process. (You cannot use wildcards in the process name.) For example:
keylogger.exe
MD5: 6A7DFAF12C3183B56C44E89B12DBEF56

- **Delete Files**—Enter the names of files to delete if the user's computer does not meet the policy requirements. (You cannot use wildcards in the file name.) Enter one filename per line. For example:
c:\temp\bad-file.txt
/temp/bad-file.txt

- **Send reason strings**—Select this option to display a message to users (called a reason string) that is returned by Host Checker or IMV and that explains why the client machine does not meet the Host Checker policy requirements. This option applies to predefined rules, to custom rules, and to third-party IMVs that use extensions in the Ivanti TNC SDK. For example, an antivirus IMV might display the following reason string:

The AntiVirus Product Version is too low. The age of the Virus Definitions is not acceptable.

4. Click **Save Changes**.

Store and Reuse Host Checker Policy Results

The Host Checker configuration page enables you to store and reuse the host checker evaluation results. The admin can configure the time interval in days for not performing the host check on the endpoint. When the user connects for the first time the Host Checker runs and the results are saved in IPS. However, for the subsequent logins from the same endpoint, the host checking is not performed and the saved host check result is reused till the expiration of the admin defined time interval.

The first connection from the endpoint never reuses the cached results. The subsequent logins from the same endpoint uses the cached host checker results.

This feature saves the Host Check results for clients connecting from Windows and Mac desktop operating systems. This feature helps in providing faster connection or access to the network.

The Host Checker saved/cached results will be cleared in the following scenarios:

- Change in HC policy configuration such as addition, deletion and modifications
- Change in Active ESAP version
- Change in HC configuration such as periodic interval, disabling the caching feature and role configuration under caching feature
- Server reboot

Limitations

- Periodic host checking, rule monitoring, and remediation are supported only for the first connection when the results are not cached
- Change in Compliance status of the device is not detected if cached results are used for the connection

To configure caching on Host Checker:

1. Select **Authentication > Endpoint Security > Host Checker**.
2. Under Options, Store host checking evaluation results enable **Store Host Checking evaluation** results and enter the number of days for not performing the Host Check. The default number of days for storing HC results is 7 days. The supported range is between 1- 30 days.

3. The Admin can also choose to cache results based on the roles assigned:

- **Any role is assigned**- If you select this option, the HC results are cached irrespective of the role assigned.
- **Any of the selected roles is assigned**- If you select this option, the HC results are cached only when the selected role is assigned.

It is recommended to not enable caching for remediation roles because the subsequent logins will be in the remediation role as cached results are used.

Host Checker

Host Checker

▼ Options

Perform check every: 10 minutes

*Client-side process, login inactivity timeout: 20 minutes min=1

☒ Auto-upgrade Host Checker

▼ Store host checking evaluation results

☒ Store Host Checking evaluation results for 7 days

Note: Enabling this option will allow the server to cache the host checking results. The cached results will be used for host checking evaluation for specified number of days, and rule monitoring and periodic host checking feature will not be applicable.

☒ Cache results if any of the roles is assigned

☐ Cache results only if any of the selected roles are assigned

Available Roles: Users, Guest Admin, Guest, Guest Sponsor, Guest Wired Restricted

Selected Roles:

Add ->

Remove

4. Click **Save Changes**.

Admission Control Using Network Security Devices

Ivanti Policy Secure also extends Admission control integrations based on alerts. IPS integrates with Next Generation firewalls for threat analysis and once that threats alerts are identified, Ivanti Policy Secure leverages syslog mechanism/REST API mechanism and takes appropriate actions on the user sessions to either terminate or change the role.

MDM Interoperability with IPS

Overview

Mobile Device Management (MDM) servers secure, monitor, manage, and support mobile devices deployed across mobile operators, service providers, and enterprises. MDM servers consist of a device authorization server that controls the use of some applications on a mobile device (for example, an e-mail application) in the deployed environment. The IPS queries the MDM servers for the necessary device attributes and evaluates them while assigning roles before giving access to the network.

For example, the MDM might detect that a device is out of compliance with IPS role mapping rules. At the next device check interval, IPS queries the MDM for updated attribute data. The compliance check is done periodically and if a formerly compliant device is now non-compliant, it assigns the device the non-compliant role and enforces the same on switch or firewall based on the IPS configuration.

Supported MDM Servers

Ivanti Policy Secure(IPS) supports the following MDM servers:

- Airwatch
- Mobile Iron
- Microsoft Intune

Ivanti Policy Secure(IPS) determines the device identifiers using the following methods:

- Device Certificate
- MAC Address

The dynamic policy evaluation feature is not used in the device access management framework.

The device-attribute-based roles are specified for the following policies:

- 802.1x network access control RADIUS return attribute policies (Layer 2)
- Infranet Enforcer resource policies (Layer 3)

MDM Integration Work Flow

The MDM integration work flow is described below:

1. The user associates a device to SSID.
2. (Optional) If the device is not registered, the user goes through the device on-boarding process.
3. Ivanti Policy Secure(IPS) queries the MDM server with device details through MAC address or device attributes.
4. The MDM server returns device attributes with which IPS uses one or more attributes to determine device access.
5. Ivanti Policy Secure(IPS) allows or denies access based on the attributes.

MDM Dictionary Attributes

This section focuses on the following elements of the MDM configuration that are important to this solution:

- **Device identifier**—The primary key for device records. Your MDM configuration determines whether a universal unique identifier (UUID), unique device identifier (UDID), or serial number is used as the device identifier.
For AirWatch, UDID is supported and recommended. For MobileIron, UUID is supported and recommended.
- **Device attributes**—A standard set of data maintained for each device. The device attributes for AirWatch, MobileIron, and Microsoft Intune are described below.

When the user installs the MDM application on the device and completes enrollment, the MDM pushes the device certificate to the device. After enrollment, the MDM maintains a database record that includes information about the enrollee—attributes related to device identity, user identity, and posture assessment against MDM policies.

Table describes these attributes. In this solution, these attributes are used in IPS role mapping that is the basis for network access and resource access policies. When you configure role-mapping rules, you specify the normalized attribute name.

AirWatch Attribute	Normalized Name	Description	Data Type
BlockLevelEncryption	BlockLevelEncryption	True if block-level encryption is enabled; false otherwise.	Boolean
ComplianceStatus	complianceReason	Values: Compliant, Non-Compliant.	String
ComplianceStatus	isCompliant	True if the status is compliant with MDM policies; false otherwise.	Boolean

AirWatch Attribute	Normalized Name	Description	Data Type
CompromisedStatus	CompromisedStatus	True if the status is compromised; false otherwise.	Boolean
CompromisedStatus	isCompromised	True if the device is compromised; false otherwise.	Boolean
DataProtectionEnabled	DataProtectionEnabled	True if data protection is enabled; false otherwise.	Boolean
DeviceFriendlyName	deviceName	The concatenated name used to identify the device/user combination.	String
EnrollmentStatus	isEnrolled	True if MDM value is Enrolled; false otherwise.	Boolean
FileLevelEncryption	FileLevelEncryption	True if file-level encryption is enabled; false otherwise.	Boolean
Id.Value	deviceId	Device identifier.	String
Imei	IMEI	IMEI number of the device.	String
IsPasscodeCompliant	IsPasscodeCompliant	True if the passcode is compliant with the MDM policy; false otherwise	Boolean

AirWatch Attribute	Normalized Name	Description	Data Type
IsPasscodePresent	IsPasscodePresent	True if a passcode has been configured; false otherwise.	Boolean
LastComplianceCheckOn	LastComplianceCheckOn	The refresh date and timestamp of the last status reported.	Timestamp
LastCompromisedCheckOn	LastCompromisedCheckOn	The refresh date and timestamp of the last status reported.	Timestamp
LastSeen	lastSeen	Date and time the device last made successful contact with the MDM.	Timestamp
LocationGroupName	LocationGroupName	MDM location group configuration value.	String
MacAddress	macAdress	The Wi-Fi MAC address.	String
Model	model	Model is automatically reported by the device during registration.	String
OperatingSystem	osVersion	OS version.	String

AirWatch Attribute	Normalized Name	Description	Data Type
Ownership	ownership	Values: C, E, or S (Corporate, Employee, or Shared).	String
PhoneNumber	phoneNumber	Phone number entered during registration.	String
Platform	platform	Platform specified during registration.	String
SerialNumber	serialNumber	Serial number.	String
Udid	UDID	Unique device identifier.	String
UserEmailAddress	userEmail	E-mail address of device user.	String
UserName	userName	Name of device user.	String
Uuid	UUID	Universal unique identifier.	String

MobileIron Attribute	Normalized Name	Description	Data Type
@id	deviceId	Device identifier.	String
blockedReason	blockedReason	Reason MDM has blocked the device. Can be a multivalued string. Values are: <ul style="list-style-type: none">AllowedAppControlPolicyOutOfComplianceAppControlPolicyOutOfCompliance	String

MobileIron Attribute	Normalized Name	Description	Data Type
		<ul style="list-style-type: none">• DataProtectionNotEnabled• DeviceAdminDeactivated• DeviceComplianceStatusUnknown• DeviceCompliant• DeviceCompromised• DeviceExceedsPerMailboxLimit• DeviceManuallyBlocked• DeviceNotRegistered• DisallowedAppControlPolicyOutOfCompliance• ExchangeReported• HardwareVersionNotAllowed• OsVersionLessThanSupportedOsVersion• PolicyOutOfDate• RequiredAppControlPolicyOutOfCompliance	
compliance	complianceReason	<p>MDM policy compliance status. Can be a multivalued string. Values are:</p> <ul style="list-style-type: none">• AllowedAppControlPolicyOutOfCompliance• AppControlPolicyOutOfCompliance• DataProtectionNotEnabled	String

MobileIron Attribute	Normalized Name	Description	Data Type
		<ul style="list-style-type: none"> • DeviceAdminDeactivated • DeviceComplianceStatusUnknown • DeviceCompliant • DeviceCompromised • DeviceExceedsPerMailboxLimit • DeviceManuallyBlocked • DeviceNotRegistered • DisallowedAppControlPolicyOutOfCompliance • ExchangeReported • HardwareVersionNotAllowed • OsVersionLessThanSupportedOsVersion • PolicyOutOfDate • RequiredAppControlPolicyOutOfCompliance 	
compliance	isCompliant	True if the device is in compliance with its MDM security policies; false otherwise.	Boolean
compliance	isCompromised	True if the device is compromised; false otherwise.	Boolean
countryName	countryName	Country name corresponding with the country code of the device.	String
currentPhoneNumber	phoneNumber	Phone number entered during registration.	String

MobileIron Attribute	Normalized Name	Description	Data Type
emailAddress	userEmail	E-mail address of device user.	String
employeeOwned	Ownership	Values: Employee or Corporate.	String
homeOperator	homeOperator	The service operator for the device when it is not roaming.	String
iPhone IMEI (iOS), imei (Android)	Imei	IMEI number of the device.	String
iPhone UDID	UDID	Unique device identifier.	String
isBlocked	isBlocked	True if the device is blocked from accessing the ActiveSync server; false otherwise.	Boolean
isQuarantined	isQuarantined	True if the device is quarantined by the MDN; false otherwise.	Boolean
lastConnectAt	lastSeen	Date and time the device last made successful contact with the MDM.	Timestamp
manufacturer	manufacturer	Manufacturer is automatically reported by the device during registration.	String
mdmManaged	mdmManaged	True if the MDM profile is enabled on the device; false otherwise. This field applies only to iOS devices. For other devices, the value is always false.	Boolean
modelName, model, device_model	Model	Model is automatically reported by the device during registration.	String
name	deviceName	The concatenated name used to identify the device/user combination.	String
operator	Operator	Service provider. The value PDA indicates no operator is associated with the device.	String

MobileIron Attribute	Normalized Name	Description	Data Type
OSVersion (iOS), os_version (Android)	osVersion	OS version.	String
platform	Platform	Platform specified during registration.	String
principal	userId	User ID.	String
quarantinedReason	quarantinedReason	<p>MDM policy compliance status. Can be a multivalued string. Values are:</p> <ul style="list-style-type: none">• AllowedAppControlPolicyOutOfCompliance• AppControlPolicyOutOfCompliance• DataProtectionNotEnabled• DeviceAdminDeactivated• DeviceComplianceStatusUnknown• DeviceCompliant• DeviceCompromised• DeviceExceedsPerMailboxLimit• DeviceManuallyBlocked• DeviceNotRegistered• DisallowedAppControlPolicyOutOfCompliance• ExchangeReported• HardwareVersionNotAllowed• OsVersionLessThanSupportedOsVersion	

MobileIron Attribute	Normalized Name	Description	Data Type
		<ul style="list-style-type: none"> PolicyOutOfDate RequiredAppControlPolicyOutOfCompliance 	
SerialNumber	serialNumber	Serial number.	String
statusCode	isEnrolled	True if the device has completed enrollment or registration; false otherwise.	Boolean
uuid	UUID	Universal unique device identifier.	String
userDisplayName	userName	Name of device user.	String
wifi_mac (iOS), wifi_mac_addr (Android)	macAddress	The Wi-Fi MAC address.	String

Intune Attribute	Normalized Name	Description	Data Type
complianceState	isCompliant	True or false (string) based on whether device is compliant or non-compliant.	Boolean
isManaged	isEnrolled	True or false (indicating whether the client is managed by Intune or not).	Boolean
macAddress	macAddress	MAC address of the device.	String
serialNumber	serialNumber	Serial number of the device. Applies to iOS Devices only.	String

Intune Attribute	Normalized Name	Description	Data Type
imei	IMEI	The device unique identifier. IMEI (15 decimal digits: 14 digits plus a check digit) or IMEISV (16 digits) includes information on the origin, model, and serial number of the device.	String
udid	UDID	The device unique identifier. Unique Device Identifier (UDID), which is a sequence of 40 letters and numbers that is specific to iOS devices.	String
meid	MEID	MEID is 56 bits long (14 hex digits). It consists of three fields, including an 8-bit regional code (RR), a 24-bit manufacturer code, and a 24-bit manufacturer-assigned serial number.	String
osVersion	osVersion	OS Version of the device.	String
model	Model	Model of the device.	String
manufacturer	manufacturer	Device Manufacturer.	String
azureDeviceId	deviceId	The device Id of the device after it has work place joined with Azure Active Directory.	String
lastContactTimeUtc	lastSeen	The date time when the device last checked in with the Intune management service endpoint.	String The format is MM/DD/YYYY HH:MM:SS

Refer to third-party documentation for complete information and configuration details.

Configuring IPS with MDM Servers

Configuring an Authentication Protocol Set

The authentication protocol set associated with the sign-in page must include the EAP method selected in the MDM Wi-Fi profile. The predefined authentication protocol set named 802.1x can be used as-is because it includes all the EAP methods currently configurable on MDMs.

To configure the authentication protocol set:

1. Select **Signing In > Authentication Protocols to display the configuration page**.
2. Click **New Authentication Protocol** or select the predefined 802.1x set. If anything other than MAC address is used as a device identifier then you must use cert auth and the protocol set has to be used for cert auth.
3. Click **Save**.

Configuring the MDM Authentication Server

The MDM authentication server configuration is used by IPS to communicate with the MDM. In the device access management framework, the MDM server is used as the device authorization server.

To configure the authentication server:

1. Select **Authentication > Auth Servers** to navigate to the authentication server configuration pages.
2. Select **MDM Server** and click **New Server** to display the configuration page.
3. Complete the configuration as described in Table below.

4. Save the configuration.

Settings	Guidelines
Name	Specify a name for the configuration.
Type	Select the MDM server.
Port Selection	Choose the communicating interface/network for each auth server independently. This enables you to communicate using Internal, external, or management interface.
Server	
Server Url	Specify the URL for your AirWatch server. This is the URL AirWatch has instructed you to use to access its RESTful Web API (also called a RESTful Web service). The URL for the AirWatch MDM server used in this example has the following form:

Settings	Guidelines
	<p>https://apidev-as.Awmdm.com https://m.mobileiron.net/pulsesecuretest</p> <hr/> <p> You must configure your firewalls to allow communication between these two nodes over port 443.</p> <hr/>
Viewer Url	<p>Specify the URL for the AirWatch report viewer. This URL is used for links from the Active Users page to the AirWatch report viewer. The URL for the AirWatch MDM viewer for this example has the following form:</p> <p><a href="https://apidev.awmdm.com/AirWatch/Devices/DeviceDetails/<deviceAttr.deviceId>">https://apidev.awmdm.com/AirWatch/Devices/DeviceDetails/<deviceAttr.deviceId> https://m.mobileiron.net/pulsesecuretest/admin/admin.html#smartphones:all</p>
Request Timeout	<p>Specify a timeout period (0-60 seconds) for queries to the MDM server. The default is 15 seconds.</p> <p>Calibrate this value based on your observations on how long a query to the MDM server takes over your network. If your network experiences latency when querying the MDM cloud service, increase the timeout to account for the latency. The system queries the MDM when a user attempts to sign in. If a timeout occurs, role mapping proceeds without attributes.</p>
Administrator	
Username	Specify the username for an account that has privileges to access the MDM RESTful Web API.
Password	Specify the corresponding password.
Tenant Code	Copy and paste the AirWatch API tenant code.
Device Identifier	
Device identity	<p>Select an option on whether to require that the MDM certificate is presented by the endpoint when signing in:</p> <ul style="list-style-type: none"> Require — Require that the device certificate pushed to client devices during enrollment be used at sign-in. If this option is selected, and the client device does not have a certificate, authorization fails. Use this option when you require endpoints to adhere to your certificate security requirements.

Settings	Guidelines
	<ul style="list-style-type: none"> Use Certificate if present — Use the certificate to derive the device ID if the certificate is presented at sign-in, but do not reject authentication if the certificate is not present. You can use this option in conjunction with a role mapping rule and a remediation VLAN to identify devices that have not perfected MDM enrollment. Always Use MAC address — In some cases, the MDM certificate might be configured without a device identifier. When the endpoint uses an 802.1x framework to authenticate, IPS can obtain the MAC address from the RADIUS return attribute callingStationID. The system can then use the MAC address as the device identifier.
ID Template	<p>Construct a template to derive the device identifier from the certificate attributes. The template can contain textual characters as well as variables for substitution. The variables are the same as those used in role mapping custom expressions and policy conditions. Enclose variables in angle brackets like this <variable>.</p> <p>For example, suppose the certificate DN is: CN= <EnrollmentUser>, serialNumber= <DeviceUid>, o=Company. With this configuration, the certificate could identify both the user and the device. In this example, the device ID template is <certDN.serialNumber>.</p>
ID Type	<p>Select the device identifier type that matches the selection in the MDM certificate configuration:</p> <ul style="list-style-type: none"> UUID— The device universal unique identifier. This is the key device identifier supported by MobileIron MDM. Serial Number—The device serial number. UDID—The device unique device identifier. This is supported by the AirWatch MDM. Device ID - This is the key device identifier supported by Microsoft Intune.

Configuring the Certificate Server

The certificate server configuration enables device users to authenticate using the certificate pushed to the device by the MDM. The certificates are used for user authentication, and the users do not have to enter user credentials.

To configure authentication with the certificate server:

- 1. Select **Authentication > Auth. Servers**.
- 2. Select **Certificate Server** and click **New Server** to display the configuration page.
- 3. Complete the configuration as described in table below.
- 4. Save the configuration.

* indicates required field

Settings	Guidelines
Name	Specify a name to identify the server within the system.

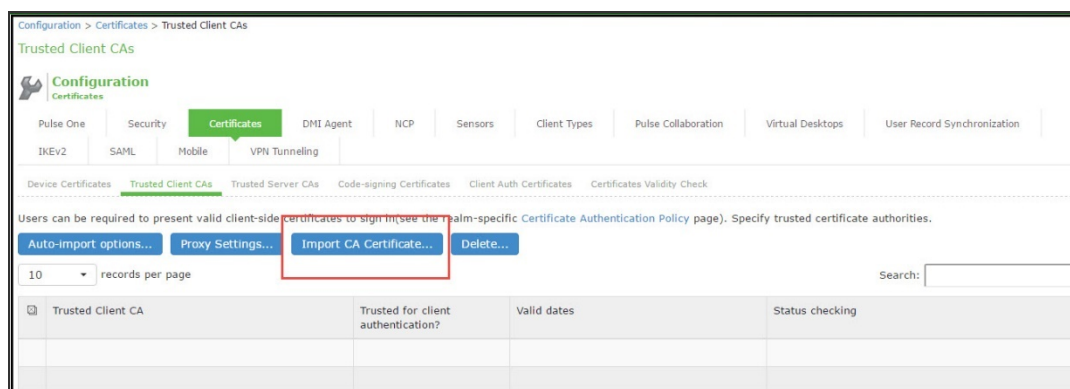

Settings	Guidelines
User Name Template	<p>Specify a username template. Specify how the system should construct a username. You may use any combination of certificate variables contained in angle brackets and plain text. The username template you configure must be consistent with the MDM certificate template configuration. Your goal is to identify the values specified in the MDM certificate that are to be used as the username in IPS system. This value populates the <USER> and <USERNAME> session variables for use throughout the rest of the system configuration.</p> <p>For example, suppose the certificate DN is: CN=<EnrollmentUser>, serialNumber=<DeviceUid>, o=Company. With this configuration, the certificate could identify both the user and the device. In this example, the username template is <certDN.CN>.</p>

Adding the MDM Certificate to the Trusted Client CA Configuration

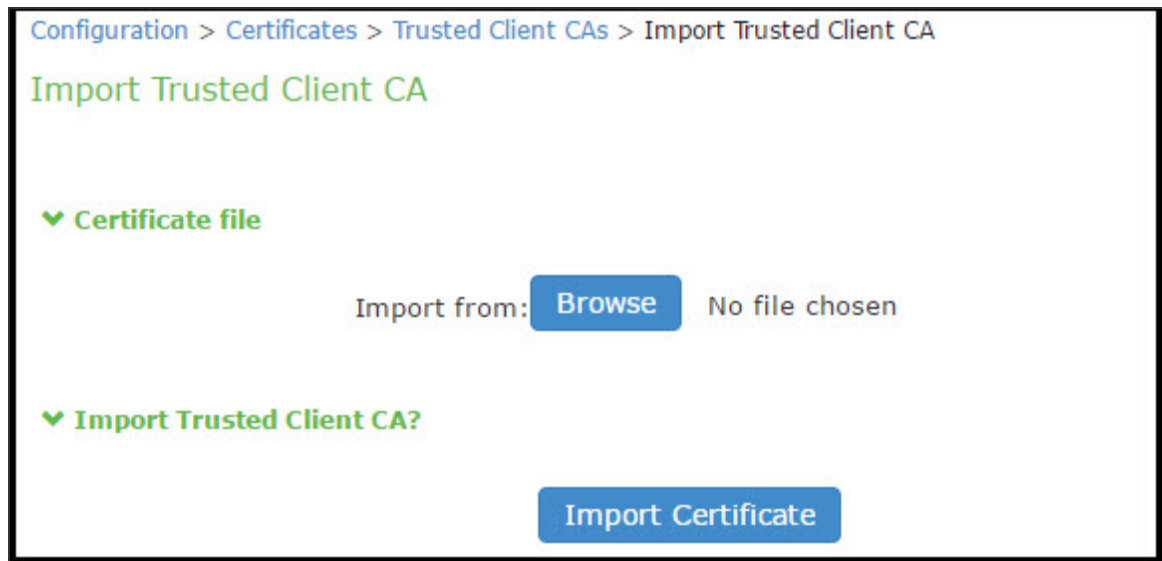

The system uses the uploaded certificate to verify that the browser-submitted certificate is valid. You must upload the MDM certificate that signed the client certificate that was pushed to the mobile devices. Typically, you obtain this certificate from the MDM when your company establishes its account with them.

To import a trusted client CA certificate:

1. Select **System > Configuration > Certificates > Trusted Client CAs**.

2. Click **Import Trusted Client CA Certificate**.

3. Browse to the certificate file, select it, and click Import Certificate to complete the import operation.
4. Click the link for the Trusted Client CA to display its details.

Configuring User Roles

User roles are classifiers for network access control policies. You create a set of roles to use in your classification scheme: device status is MDM enrollment complete or incomplete; device status is MDM-policy compliant or noncompliant; device is employee owned or company owned; device platform is iOS, Android, or neither; and so forth.

The user role configuration also includes options to customize user interface features that are appropriate for a particular role. For MDM deployments, you can use the Personalized Greeting UI option to send a notification message to the device when the role has been applied.

To configure user roles:

1. Select **Users > User Role** to navigate to the role configuration page.
2. Click **New Role** to display the configuration page.
3. Complete the configuration for general options as described in below table.
4. Save the configuration.
5. Click **UI options** to display the configuration page.

6. Complete the configuration for UI options as described in below table.
7. Save the configuration.
8. Click **Session Options** to display the configuration page.
9. Complete the configuration for session options as described in below table.
10. Save the configuration.
11. Click **Agentless** to display the configuration page.
12. Complete the configuration for agentless options as described in below table.
13. Save the configuration.

Settings	Guidelines
Overview tab	

Settings	Guidelines
Name	Specify a name for the configuration.
Description	Describe the purpose of the role so that other administrators are aware of it.
Options	Select UI Options so that you can customize a message to be sent to the device when the role is applied.
UI Options tab	
Personalized greeting	<p>Select the Show notification message option and enter a message to be sent to the device (through the MDM API) after sign-in and this role has been applied, or after role reevaluation if it results in a role change to this role.</p> <p>In this example, we are using the system to enforce MDM enrollment by flagging compromised devices. The message, therefore, is:</p> <p>Your device is compromised. Network access may be limited.</p> <p>The message is forwarded to the device using the MDM server Push Notification feature.</p> <p>The content of your notification message can vary depending on whether the switch or access point supports change of authorization (CoA). If the CoA is supported, reauthentication is automatic, so your message might simply state that "your level of access has changed." If CoA is not supported, reauthentication needs to be done manually by the user in which case the message might state that "your level of access has changed, please reconnect."</p> <p>NOTE: When multiple roles are assigned, UI options are not merged. The UI options for the first role that matches are applied.</p>
Session Options	
Allow VPN Through Firewall	Enable this option to allow Infranet Enforcer traffic to act as a heartbeat and keep the session alive. This option is useful for iOS devices.
Agentless	
Enable agentless access	Select this option for roles that you provision to access the network from BYOD devices. The solution that integrates with MDMs depends on the native supplicant, not an Ivanti agent.

Configuring a Realm and Role Mapping Rules

The user realm configuration associates the authentication server data and MDM server data with user roles.

To configure the realm and role mapping rules:

1. Select **Users > User Realms > New User Realm** to display the configuration page.
2. Upon saving the new realm, the system displays the role mapping rules page.
3. Click **New Rule** to display the configuration page.
4. Complete the configuration as described in table.
5. Click the **Authentication Policy** tab and then click the **Certificate subtab** to display the certificate restriction configuration page.

Settings	Guidelines
Name	Specify a name for the realm. If you enable sign-in using a realm suffix in the sign-in policy configuration, the realm name must match the username realm suffix configured in the MDN Wi-Fi profile.
Description	Describe the purpose of the realm so that other administrators are aware of it.
Servers	
Authentication	Select the user authentication server for this realm's users. This example uses the certificate server configured in the earlier step. When you use a certificate server, users are not prompted for their credentials. You can also select the authentication server used for employees. In that case, users are prompted by the sign-in page to provide their username and password.
User Directory/Attribute	This option is not used.
Accounting	This option is not used.
Device Attributes	Select the MDM server configured for device authorization.

Settings	Guidelines
Device Check Interval	<p>Select this feature to leverage the MDM posture assessment checks and enforce compliance. For example, the MDM might detect that a device is out of compliance with its security policies, such as a password policy. At the next device check interval, IPS queries the MDM for updated attribute data. In this example, it learns that a formerly compliant device is now noncompliant. It assigns the device the noncompliant role and sends the 802.1x authenticator the corresponding RADIUS attribute to place it in a remediation VLAN.</p> <p>Specify the interval at which to query the MDM for updated attribute data. Specify 0 to disable periodic queries. The minimum is 10 minutes and the maximum is 10080 minutes (7 days).</p> <p>Specify an interval that is appropriate for the MDM. Some MDMs, for example, update records every 4 hours, so a 10-minute interval would not be productive.</p>
Dynamic Policy Evaluation	
Dynamic Policy Evaluation	This option is not used.

Limits

☒ Allow all users (no client-side certificate required)

☐ Allow all users and remember certificate information while user is signed in.

☐ Only allow users with a client-side certificate signed by Trusted Client CAs to sign in. To change the certification authority, see the [Trusted Client CA](#) page

You can optionally require specific values in the client certificate:

10

 records per page

Certificate field (example "cn")	Expected value
<input type="text"/>	<input type="text"/>
<input type="text"/>	<input type="text"/>
<input type="text"/>	<input type="text"/>
<input type="text"/>	<input type="text"/>

Save Changes

Settings	Guidelines
Allow all users	Do not select this option. If you select this option, the system does not request a client certificate during the TLS handshake.
Allow all users and remember certificate	If you select this option, the system requests a client certificate during the TLS handshake. It does allow endpoints to authenticate without a client certificate. For those with a client certificate, the certificate attributes are placed in the session context.
Only allow users with a client-side certificate	If you select this option, the system requests a client certificate during the TLS handshake. It does not allow endpoints to authenticate without a valid client certificate. If the realm is configured with a certificate server, like this example, this option is the only option that can be selected.

Configuring a Sign-In Policy

A sign-in policy associates devices with a realm.

To configure a sign-in policy:

1. Select **Authentication > Signing In > Sign-In Policies** to navigate to the sign-in policies configuration page.
2. Click **New URL** to display the configuration page.
3. Complete the configuration as described below.
4. Save the configuration.

Settings	Guidelines
User type	Select Users.
Sign-in URL	Enter a URL.
Description	Describe the purpose of the sign-in policy so that other administrators are aware of it.
Sign-In Page	Select a sign-in page.
Authentication Realm	
Realm	Select the realm you configured in the earlier step.
Authentication Protocol Set	Select the protocol you configured in the earlier step.
Realm name as a username suffix	<p>Select this option if the username sent during sign-in includes a realm suffix. To use this option, the realm name must match the username realm suffix configured in the MDN Wi-Fi profile.</p> <p>This configuration enables you to dedicate the realm to the MDM traffic. Non-MDM traffic passing through the same switch then belongs to a different realm.</p> <p>NOTE: In some cases, you can use authentication protocol sets to segregate traffic into a particular realm. For example, assuming only mobile endpoints use TLS and other endpoints do not, an authentication protocol set containing only TLS can be created and associated with a particular realm through a sign-in policy.</p>

Settings	Guidelines
Remove realm suffix	Remove the realm suffix within system processes, such as rule processing and logs.

Configuring IPS with Microsoft Intune

Microsoft Intune is an MDM server which provides the device compliance status for the mobile devices. IPS retrieves the device attributes from Microsoft Intune and uses it for compliance assessments and role assignment. This feature integrates Microsoft Intune and IPS for providing compliance check and onboarding of devices.

To configure Microsoft Intune MDM server:

1. Select **Authentication > Auth. Servers > New MDM Server**.
2. Enter the server name, select Microsoft Intune as MDM.
 - Enter the Azure AD Tenant ID.
 - Enter the Web application ID or Client ID that is registered in Azure AD.
 - Enter the Client Secret key registered in the Azure AD.
 - Enter the Timeout duration in seconds. Default is 15 seconds.

To obtain Tenant ID, Client ID, Client Secret Key, see [Viewing Client ID, Tenant ID, and Client Secret](#).

3. Click **Save changes**.

Configuring the Microsoft Intune MDM

Microsoft Intune acts as the Mobile Device Management (MDM) Server for IPS solution. IPS users have to register their mobile devices with Microsoft Intune. As part of registration, the relevant Profiles get automatically provisioned to mobile device.

To configure the Microsoft Intune MDM:

1. Enroll the devices with the MDM server.
2. Create an enterprise WiFi profile.

3. Configure IPS with a role and realm for the user. Microsoft Intune provides the user with a link to provision the created policy and then pushes the profile information. IPS does the role assignment and either allows or denies based on the device assessment. For more information, see [Configuring IPS](#)
4. Create Azure Active Directory (AAD) web application.
5. Go to portal.azure.com, click on the Azure Active Directory on the left of the screen, click on to App registrations and click on New application registration.

6. Enter the application name, select Web app/API as application type, and enter the IP address/FQDN for sign-on-URL and Click Create.

7. Click the application and select the required permissions and click **Add**.

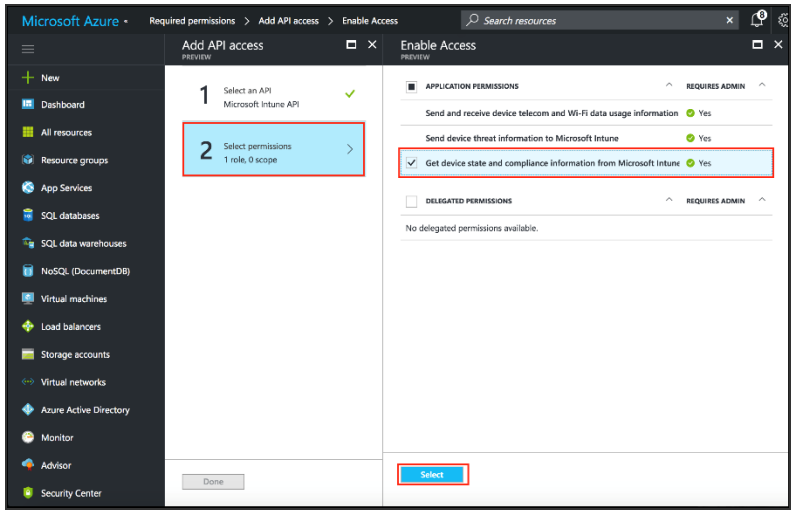

8. Click **Grant Permission**.

9. Select **Microsoft Intune API**.

Under Application Permissions, select Get device and compliance information from Microsoft Intune.

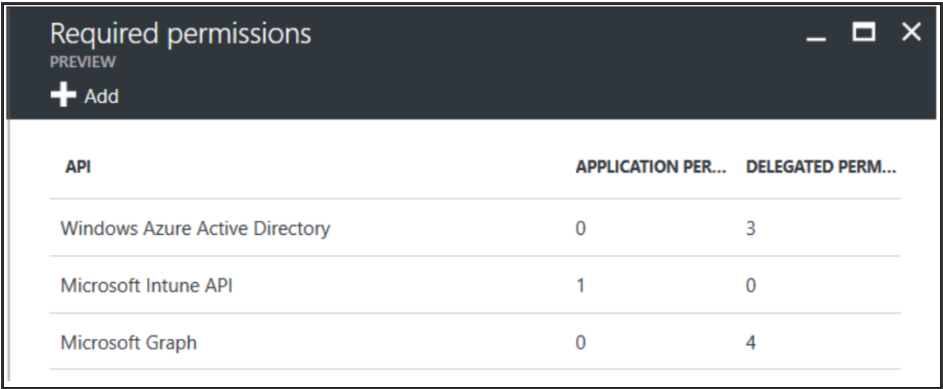

10. (Optional) You must add the following delegated permissions for Microsoft Graph API.

- Sign in and read user profile
- Sign Users in
- View users’ email address
- View users’ basic profile

11. (Optional) Add the following delegated permissions for Azure Active Directory.

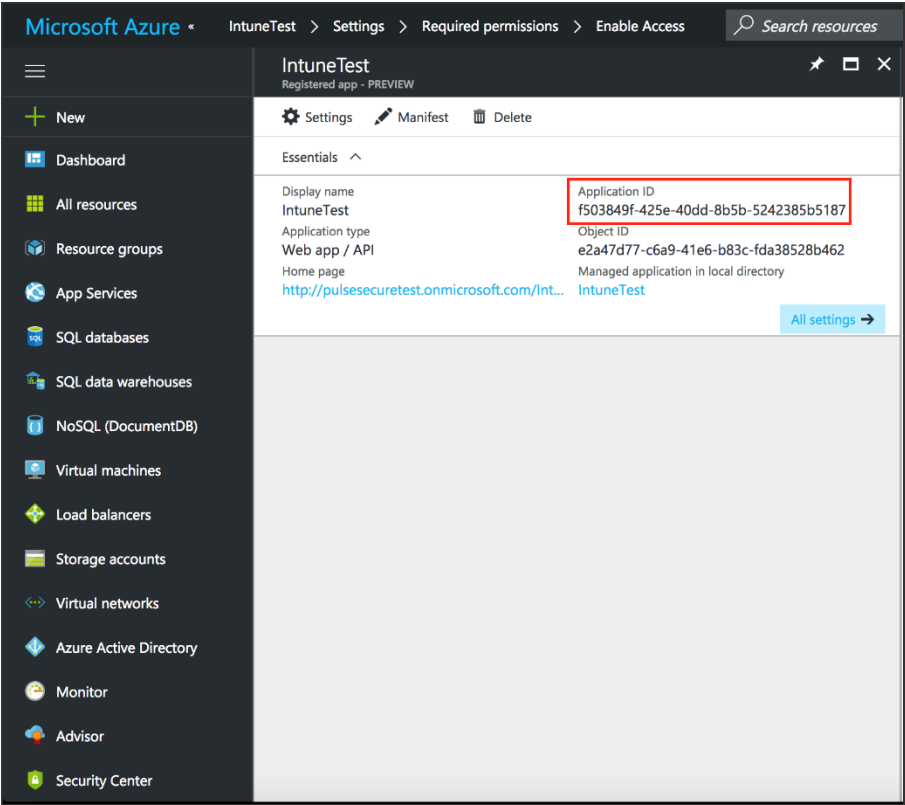

- Sign in and read user profile
- Read all users' basic profiles
- Access the directory as the signed-in user.

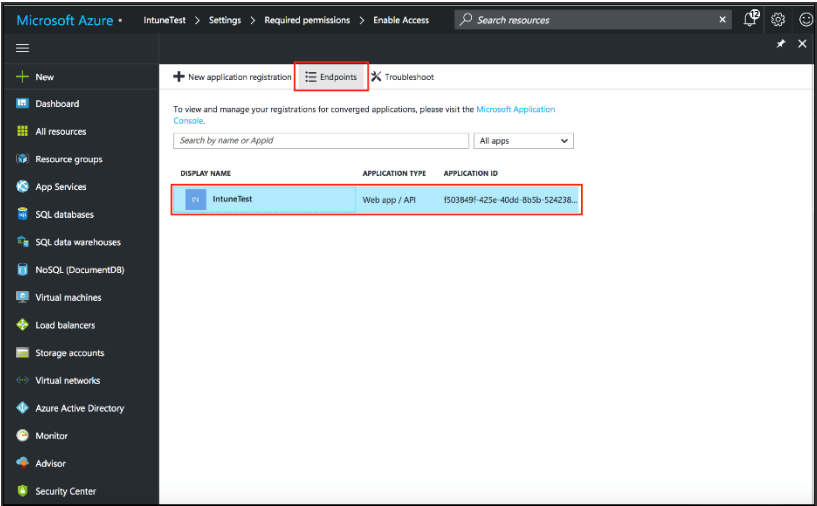

API	APPLICATION PER...	DELEGATED PERM...
Windows Azure Active Directory	0	3
Microsoft Intune API	1	0
Microsoft Graph	0	4

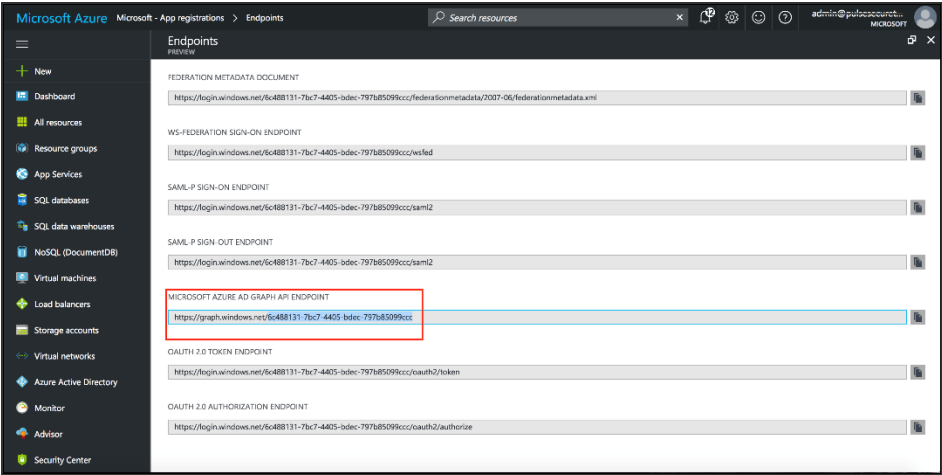

Viewing Client ID, Tenant ID, and Client Secret

The Client ID/Application ID is created automatically once the AAD web application/API is created. You can view the client ID/application ID from the application properties page.

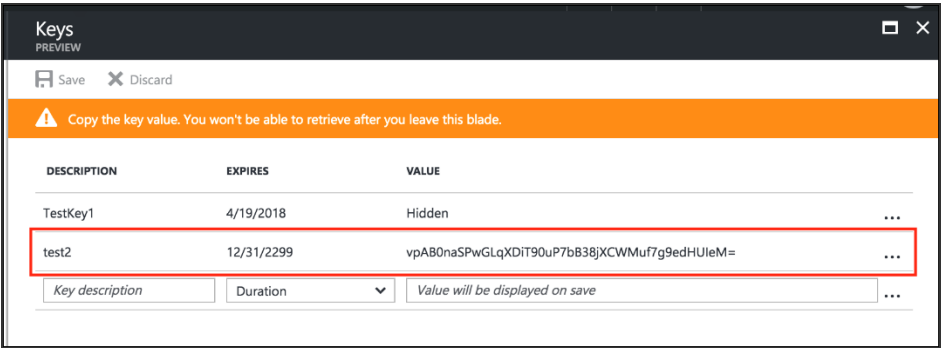

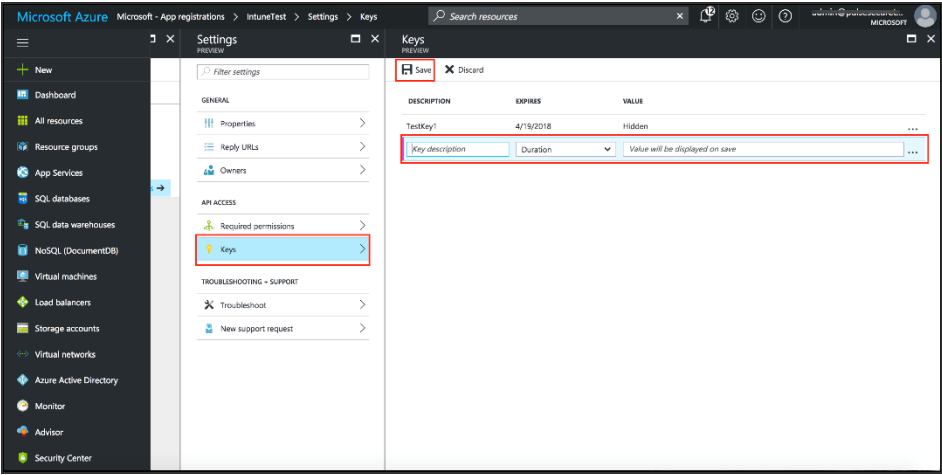

Every organization in Microsoft cloud is called tenant and it is organization specific. Each Tenant will be having a unique Tenant ID. Select the web application/API and click Endpoints tab and then you can copy the tenant ID.

To create the secret key, click the Web Application/API and then click Keys.

Configuring the AirWatch MDM

To configure the AirWatch MDM:

1. Enroll devices in the MDM using the methods supported by the MDM.
2. Create a profile with the following MDM management options:
 - Certificate template- Create a configuration that specifies the field and type of identifier for client device certificates.

The MDM configuration templates provide flexibility in how the device identifier can be placed in the device certificate's subject or alternative subject. We recommend you include the user ID in the certificate, so the certificate can identify both the user and the device. For example:
CN= <EnrollmentUser>, serialNumber= <DeviceUid>, o=Company
 - Credential profile- Create a configuration that specifies the certificate authority and certificate template configuration.
 - Wi-Fi profile- Create a configuration that specifies the SSID, security options, and the credential configuration.
3. Save and deploy the profile to devices registered with your organization.
4. Enable API access and generate the AirWatch API key (tenant code).

The tenant code is part of the REST API configuration. The tenant code must be included in IPS MDM server configuration.

Configuring the MobileIron MDM

To configure the MobileIron MDM:

1. Enroll devices in the MDM using the methods supported by the MDM.
2. Create a Simple Certificate Enrollment Protocol (SCEP) configuration that specifies the field and type of identifier for client device certificates.
The MDM configuration templates provide flexibility in how the device identifier can be placed in the device certificate's subject or alternative subject. We recommend you include the user ID in the certificate, so the certificate can identify both the user and the device. For example:
CN=<DEVICE_UUID>, uid=<USER_ID>, o=Company
3. Create a Wi-Fi configuration that specifies the SSID and security options. During the enrollment process, this profile is provisioned to the device. Select the SCEP configuration completed in Step 2.
4. Select the Wi-Fi Profile configuration and apply it to a group label you have provisioned to manage this group of devices.

Wi-Fi connect fails if it is configured to use a device certificate that is signed by an intermediate CA and selects this in Wi-Fi profile trusted CA. Root CA has to be selected to properly work.

5. Apply the group label to the devices when you add them to the MDM. If they have already been added to the MDM, use the edit configuration utilities in the device inventory page to apply the group label.

Pulse TME	PDA 6 iPad, 3rd gen	iOS 6.1	United States	Active	2013-07-15	55 m 39 s	C	AT&

Troubleshooting

During initial configuration, enable event logs for MDM API calls. You can use these logs to verify proper configuration. After you have verified proper configuration, you can disable logging for these events. Then, enable only for troubleshooting.

To enable logging for MDM API calls:

1. Select **System Log/Monitoring**.
2. Click the **Events** tab.
3. Click the **Settings** tab to display the configuration page.

After you have completed the MDM server configuration, you can view system event logs to verify that the polling is occurring.

To display the Events log:

1. Select **System Log/Monitoring**.
2. Click the **Events** tab.
3. Click the **Log** tab.

Next, to verify user access, you can attempt to connect to a wireless access point with your smart phone, and then view the user access logs.

To display the User Access log:

1. Select **System Log/Monitoring**.
2. Click the **User Access** tab.
3. Click the **Log** tab.

After you have verified proper configuration, you are not likely to need to tune the authentication server configuration, the 802.1x framework, or the enforcement points. However, based on user experience, MDM capabilities, and security threats, there are a few configuration elements you might want to tune from time to time.

Table describes these configuration elements.

Configuration Element	Tuning
Remediation	<p>In a network access control solution, noncompliant endpoints are typically placed in a remediation VLAN that serves a Web page. The Web page explains the steps users can take to make their endpoints compliant so that they can access the network.</p> <p>Your reasons for denying access might change from time to time. For example, your initial policy might be based on compliance with an MDM policy, and you can give steps on how to bring a device into compliance. You want to set an expectation on how long it takes for the MDM to reassess compliance. You might want to factor in IPS device check interval to estimate how long until the device can access the network.</p> <p>When there are new threats that exploit vulnerabilities in specific mobile platforms, you might create rules on the fly that deny access from specific platforms. If events like this occur, you might want to update your remediation message so that users can understand why access is denied.</p>
Realm – Device Check Interval	<p>You might want to tune this setting as you learn how frequently the MDM updates device records, or if the standard practice of the MDM changes. If the MDM records are updated every four hours, it does not make sense to poll every 10 minutes. If the MDM records are updated in real time, it might make sense to poll every 10 minutes.</p>

Configuration Element	Tuning
Roles and role mapping rules	As you learn about mobile security threats and vulnerabilities, you might make changes to roles and role mapping rules or create new classifications. In general, you list restrictive rules first and set the stop flag. For example, if a device is noncompliant and maps to a noncompliant role, you would list it near the top of the rules for the realm and set the stop flag. Classification based on device type or platform can be more complicated. When you initially role out your BYOD solution, you might want to use roles to merely classify the devices, and so the rule classifying it would not need to be near the top of the list and would not need to have a stop flag. In response to a threat, however, you might want to use the role and role mapping configuration to deny access from a specific device platform. If events like this occur, you can edit your rules to map the vulnerable platform to an appropriate role and set the stop flag so that permissive roles are not assigned.
RADIUS return attribute policy	Likewise, in response to threats and vulnerabilities, you can edit your rules to place formerly trusted device types into a remediation or guest VLAN instead of an employee VLAN; and then allow access again when you are no longer concerned with the threat.
Infranet Enforcer resource access policy	Likewise, in response to threats and vulnerabilities, you can edit your rules to deny access from formerly trusted device types; and then allow access again when you are no longer concerned with the threat.

Using the Debug Logs

The Ivanti Global Support Center might direct you to create a debug log to assist them in helping you debug an issue with the system. The debug log is used only by PSGSC.

To use debug logging:

1. Select **Troubleshooting > Monitoring > Debug Log** to display the configuration page. Complete the configuration as described in table below.
2. Click Save Changes. When you save changes with **Debug Logging On** selected, the system begins generating debug log entries.

3. Initiate the action you want to debug, such as a user sign in. You can reset the debug log file to restart debug logging if it takes you too long to initiate the action.
4. Click **Save Debug Log** to save the debug log to a file that you can send to PSGSC. You can clear the log after you have saved it to a file.
5. Clear the Debug Logging On check box and click **Save Changes** to turn off debug logging.

Settings	Guidelines
Current Log Size	Displays the size of the current log file. If it is large, use the controls to save, reset, or clear the log file.
Debug Logging On	Select to turn on debug logging.
Debug Log Size	Specify a maximum debug logfile size. The default is 2 MB. The maximum is 250 MB.
Debug Log Detail Level	Specify the debug log detail level. Obtain this from PSGSC.
Include logs	Select this option to include system logs in the debug log file. Recommended.
Process Names	Specify the process name. Obtain this from PSGSC.
Event Codes	Specify the event code. Obtain this from PSGSC. For MDM integration issues, PSGSC typically likes to collect debugging information for codes MDM, Auth, agentman, and Realm. The text is not case sensitive.

AAA Servers

AAA Server Overview

Overview

AAA stands for authentication, authorization, and accounting. An AAA server is a database that stores user credentials—username and password—and, in some cases, group information or other user attributes. The authentication results and group or user attribute information are used by access management framework policy for decisions.

In the access management framework, the sign-in page, realm, and AAA server configurations are associated. They determine user access and user role. A user submits credentials through a sign-in page, which specifies a realm, which is associated with a AAA server. If the access request meets the realm's authentication policy, the system forwards the user's credentials to the associated authentication server. The authentication server's job is to verify the user's identity. After verifying the user, the authentication server sends approval. If the realm also uses the server as a directory/attribute server, the AAA server sends the user's group information or other user attribute information. The access management framework then evaluates the realm's role-mapping rules to determine the user roles that apply to the session.

The access management framework supports the following types of AAA servers:

- **Local**—You can create special purpose local databases to manually create user accounts, manage guest user access, permit anonymous access, or manage access based on digital certificates or MAC addresses.
- **External (standards-based)**—You can integrate standards-based LDAP and RADIUS servers with the access management framework. In addition to using the backend server for authentication, you can use LDAP group and RADIUS attribute information in role-mapping rules.
- **External (other)**—You can integrate compatible versions of popular third-party AAA servers with the access management framework. In addition to using the backend server for authentication, you can use Active Directory group information. In addition, you can use MDM device attributes in role mapping rules.

The following table is a reference of the AAA servers supported in IPS deployments.

	IPS
Local	Local Authentication Server Overview Certificate Server Overview MAC Address Authentication Server Overview *Special features to manage guest users. Anonymous Server Overview SAML Server Overview Access Control with SAML Server
External (standards-based)	LDAP Server Overview RADIUS Server Overview OAuth Servers Overview
External (other)	Active Directory Feature Support RSA Authentication Manager Overview SQL Auth Server Overview ACE Server Overview

Authentication Protocols Used by AAA Servers

Policy Secure supports multiple authentication protocols. The following authentication servers require the protocols listed:

- **Local authentication servers**—If the passwords are stored as hashed values, the protocols available are PAP and MS-CHAP v1 with or without EAP. If the passwords are stored as clear text, CHAP and MD5-Challenge are also available.
- **Active directory**—The protocols available for inner authentication are PAP, MSCHAP and MS-CHAP v2, with or without EAP.
- **LDAP**—CHAP, EAP-MD5-Challenge, MS-CHAP v1, and MS-CHAP v2 protocols can be used with an LDAP authentication server only if the administration password is in clear text. By default, challenge response protocols are disabled for LDAP servers. Use these protocols only with noninteractive devices (for example, phones), as password management is not possible if these protocols are used for authentication.

AAA Traffic Management

From 9.0R3 release, the IPS Virtual appliances and the Physical Appliances allow the administrator to choose the communicating interface or the network for each authentication server.

This feature allows the AAA traffic across the following interfaces:

- Physical internal
- Physical external
- Physical management
- Virtual ports for physical interfaces
- VLAN ports
- Virtual ports on VLAN interfaces

This feature allows to connect to remote supported authentication servers through any interfaces based on the network topology.

The following Authentication server types are supported:

- LDAP
- Active Directory
- RADIUS

Configuring AAA Traffic Management Across Interfaces

1. Select **Authentication > Auth Servers** and configure service provider AAA configurations as needed.

The screenshot shows the 'Authentication Servers' configuration page. At the top, there is a green header 'Authentication Servers'. Below it is a blue button labeled 'Enable Auth Traffic Control'. Underneath, there is a 'New:' label followed by a dropdown menu showing '(Select server type)'. To the right of the dropdown are two blue buttons: 'New Server...' and 'Delete...'. At the bottom left, there is a dropdown menu showing '10' and the text 'records per page'.

2. Click **Enable Auth Traffic Control**. A new window appears.

Confirm Traffic Decoupling Enabling

Warning: Enabling Traffic Decoupling can lead to user authentication failure if Auth Servers are not reachable via configured interfaces

Enable Traffic Decoupling **Cancel**

3. Click **Enable Traffic Decoupling** to confirm. The page navigates to the Auth server page that displays the options to configure the AAA traffic interfaces.

i For external port, it enables the external port to respond to incoming RADIUS client requests on the external port as well as communicate with authentication servers through that port.

Settings Users Troubleshooting

▼ Base Configuration

* Name: Label to reference this server

* Domain: NetBIOS name of the domain

* Kerberos Realm: Specifies the Kerberos realm of the Active Directory domain.
It is usually set to the DNS name of the Active Directory domain. Example "xyz.net", "abc.com"

▼ Port Selection

Set the port for reaching to Auth Server

PPS-129-PRI External

PPS-123-SEC Internal

6. Click **Save**.

AAA Server Configuration Task Summary

To integrate an authentication server:

1. Configure the authentication server. Select **Authentication > Auth. Servers page** and complete the authentication server configuration.
2. Create an authentication realm. Select **Users > User Realms** or **Administrators > Admin Realms** and select the authentication server when you complete the authentication realm configuration.

Using the Local Authentication Server

This topic describes the local authentication server.

Local Authentication Server Overview

The local authentication server is an authentication database that is built in to IPS. Therefore, it is considered a “local” server in contrast to a third-party enterprise AAA server that is connected over the network.

Typically, you create local user accounts for temporary users who do not have accounts on your enterprise AAA servers. Temporary users include lab users or guests, but you might find the local authentication server useful to create temporary accounts for users who are normally verified by an enterprise AAA server that you plan to disable.

You also use the local authentication server to create accounts for administrator users, such as system administrators and guest user access managers (GUAM).

Although it is common practice to use the local authentication server for administrator accounts, it does not preclude you from using any of the supported third-party enterprise AAA servers in your administrator access management framework.

The following authentication protocol sets can be used with the local authentication server:

- By default, the system uses hashing to store passwords. When using the default, the protocols available are PAP and MS-CHAP v1 with or without EAP.
- You can enable an option to store passwords as clear text. If you enable this option, CHAP and MD5-Challenge are also available.

Configuring the Local Authentication Server

You can create multiple local authentication server instances. When you define a new local authentication server, you must give the server a unique name and configure options for passwords and guest users.

To create a local authentication server:

1. Select **Authentication > Auth. Servers**.
2. Select **Local Authentication** and click **New Server** to display the configuration page.
3. The Local Authentication Server configuration page.
4. Complete the configuration as described in table.
5. Save the configuration.

Auth Servers > New Local Authentication

New Local Authentication

*Name: Label to reference this server.

✓ Password Options

Minimum length: characters
Maximum length: characters

☐ Password must have at least digits
☐ Password must have at least letters
☐ Password must have mix of UPPERCASE and lowercase letters
☒ Password must be different from username
☒ New passwords must be different from previous password

Password Storage Type

☒ Strong Hash This option can only be set during create.
Note: Highly secure, but not compatible with some of the authentication protocols i.e. CHAP, EAP-MD5 and MS-CHAP (V1/V2)

☐ Legacy Hash This option can only be set during create.
Note: Compatible with MSCHAP(v1/v2) although less secure

☐ Clear Text This option can only be set during create.
Note: Compatible with all authentication protocols i.e. CHAP, EAP-MD5, MSCHAP(v1/v2) although not secure

✓ Password Management

☒ Allow users to change their passwords
☐ Force password change after days
☐ Prompt users to change their password days before current password expires

Note: Use options on the Administrators/Users > Authentication > [Realm] > Authentication Policy > Password page to specify which realms should inherit the server's password management capabilities

✓ Account Lockout

☐ Enable Account Lockout for users
Maximum wrong password attempts: (3 and above)
Account Lockout period (minutes): (10 and above)

✓ Guest Access

Guest User Account Managers

☐ Enable Guest User Account Managers to administer Guest Accounts Configure system GUAM settings
Instructions for Guest User Account Manager:
You can use
,
, <code>, <code>, and to format the text.

☐ Maximum Account Validity Period: Set the Guest Account length limit (end time minus start time) in hours. This is valid for guests created by Guest Admin. Does not impact existing user expirations.

Guest Self-Registration

Send guest user credentials via: ☐ SMS Configure SMS/Email settings
☐ Email Configure SMS/Email settings
☐ Show credentials on screen after guest completes registration
☐ Enable Sponsored Guest Access
☐ Maximum Account Validity Period for Self Registered Guests: Set the Guest Account length limit in hours. This is valid for self registered guests. Does not impact existing user expirations.

Note: To enable Guest Self-Registration navigate to Signing In > Sign-in Policies > User URLs > [url] > Configure Guest Settings

Common configuration for Guest User Account Managers and Guest Self-Registration

Guest User Name Prefix: Prefix applied to auto-generated user names.

Guest User Info Fields:

✓ Server Catalog

To Enable Attribute Editing, please save Local Server Configuration.

* indicates required field

Settings	Guidelines
Name	Specify a name that is useful to you.
Password Options	

Settings	Guidelines
Minimum length	Specify a number of characters. The valid range is 0-99. 6 is the default.
Maximum length	Specify a number of characters. The valid range is 0-99. 8 is the default. The maximum length cannot be less than the minimum length.
Minimum digits	Specify the number of digits required in a password. Do not require more digits than the value of the maximum length option.
Minimum letters	Specify the number of letters required in a password. Do not require more letters than the value of the maximum length option. If you enable the previous option, the combined total of the two options cannot exceed that of the value specified in the maximum length option.
Uppercase and lowercase required	<p>Select this option if you want all passwords to contain a mixture of uppercase and lowercase letters.</p> <hr/> <p> Require passwords to contain at least two letters if you also require a mix of uppercase and lowercase letters.</p> <hr/>
Special Characters	Select this option if you want password should contain any special characters
Password Position	Select this option to validate the new password with old password based on password position. Default is 8 positions, example: If previous password is test12345678, then change password cannot be aeph 2345 . The matched characters based on position are highlighted.
Different from username	Select this option if the password cannot equal the username.
Different from previous password	Select this option if a new password cannot equal the previous password.
Password Storage Hash	
Strong Hash	Select this option to protect passwords using stronger hash algorithm for high security.

Settings	Guidelines
	<p> This option is not compatible with some of the protocols such as CHAP, EAP-MD5 and MS-CHAP (V1/V2). For Native Supplicant this option is supported only with PAP protocol.</p> <p>On upgrading IPS from previous version to 9.1R4 version there is no change in the password storage type and all the local authentication servers from previous release will be moved to newer release with same password storage type. After upgrading IPS to newer version, administrator has an option to switch to Strong hash if the previous password storage type is Legacy hash.</p> <ul style="list-style-type: none"> • After switching to strong hash, all the existing users still use the legacy hash as password. To migrate to strong hash, users need to reset their password. • After switching to strong hash, any new users created will use strong hash for the password.
Legacy Hash	Select this option to protect passwords using MS-CHAP (V1/V2).
Clear text	<p>Select this option if you are using open authentication protocol sets. CHAP and EAP-MD5-Challenge work with local authentication servers only if you select this option.</p> <p> Be aware of the security implications of storing passwords as clear text.</p>
Password Management	
Allow users to change passwords	<p>Select this option if you want users to be able to change their passwords.</p> <p> In addition to selecting local authentication password management options, you must select the Enable Password Management option for the associated realm authentication policy.</p>
Force password change	Select this option to specify the number of days after which a password expires. The default is 64 days.
Prompt users to change password	Select this option to specify when to prompt the user to change passwords.

Settings	Guidelines
Guest Access Configurations	
Enable Guest User Account Managers	Select this option to allow guest user account managers to create guest user accounts on the local authentication server. In some businesses, you might want to delegate responsibility for temporary or guest users to a guest user access manager (GUAM) who can use the local authentication server to provision accounts for guests.
Guest User Name Prefix	Specify the prefix to be used in auto generated guest usernames. We recommend you retain the default guest_ so that you can rely on the naming convention in your role mapping rules.
Guest User Info Fields	(Optional) Add line items to represent fields that you want to appear on the configuration page for creating guest user accounts. For example, you can create fields for Company Name, Host Person, Meal Preference, and so on.
Instructions for Guest User Account Manager	(Optional) Add instructions to the GUAM that appear on the GUAM sign-in page. You can use the following HTML tags to format the text: , , , <noscript>, and <a href>.
Maximum Account Validity Period	Specify the number of hours the account is valid. The default is 12 hours.
Server Catalog	
Attributes	The Attributes button appears after you have saved the server information. Click the Attributes button to display the server catalog. Configure the attribute value.

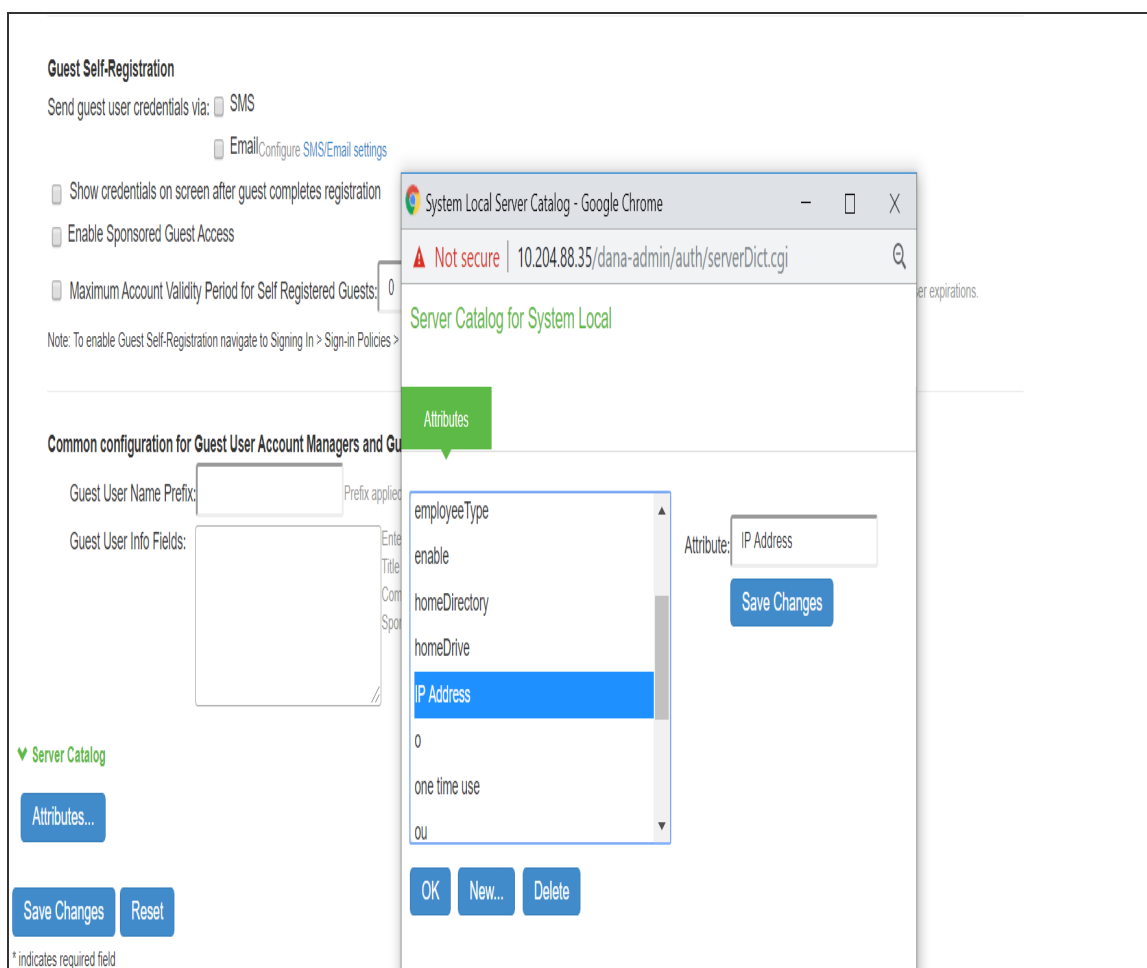

Defining Framed-IP Address

The Framed-IP attribute can be used in usecases, such as Access Point Name (APN), which manages the modems in broadband service provider network.

APN is added as a RADIUS client and it can authenticate the modem MAC addresses with Ivanti Policy Secure and assign IP Addresses associated with respective IP address configured on IPS.

To define Framed-IP attribute:

1. Select **Authentication > Auth.Servers** and select the local authentication server.
2. Under Server Catalog, Click **Attributes** and create the attributes. For example, IP Address.
3. Navigate to the users page, create new user and set attribute values.
4. Navigate to **Endpoint > Network Access > Radius Attributes > RADIUS Return Attributes**.
5. Set the Auth Server Catalog Attribute Value (userAttr.Framed-IP).
6. Click **Save Changes**.

Control the Access

Access can be controlled using the VLAN Id, ACLs and Radius Return Attribute settings below

☐ Control using VLAN Id: (1-4094)

☐ Control access using Access Control List (ACL) settings (Supported only for Cisco, Juniper, HP)

☒ Control access using Radius Return Attributes

Note: Selecting this option enables control of the device or user access

Note: This option is used for assigning devices to corresponding VLANs on the switch

Note: These attributes are sent to switch for controlling the access

Delete

Return Attribute	Radius Auth Server Attribute Value	Auth Server Catalog Attribute Value	Value	
<input type="text" value="Filter-Id"/>	<input type="text" value="-none-"/>	<input type="text" value="-none-"/>	<input type="text"/>	<div>Add</div>
<input checked="" type="checkbox"/> Framed-IP-Address	<input type="text" value="-none-"/>	<input type="text" value="IP Address"/>		
<input checked="" type="checkbox"/> Framed-IP-Netmask	<input type="text" value="-none-"/>	<input type="text" value="subnet mask"/>		

Creating User Accounts

You use the Users page to create local authentication server user accounts. A user account includes a username and password to be used for authentication, as well as other information used for records and account management.

To create a local user account:

1. Select **Authentication > Auth. Servers**.
2. Select the local authentication server to which you want to add a user account.
3. Click the **Users** tab.
4. Click **New** to display the configuration page.
5. Complete the configuration as described in table.
6. Save the configuration.

Auth Servers > Demo-Local-Auth-Server > Users > Update Local User demouser

Update Local User demouser

Save Changes

Settings	Guidelines
Username	<div>Do not include "~" in a username.</div> <div><div>i</div>You cannot change a username after you create the account.</div>
Full Name	Specify the user's full name.
Password	Specify a password. Make sure that the password you enter conforms to the password options specified on the local authentication server configuration page.
Confirm password	Confirm the password.

Settings	Guidelines
Start Time	(Optional) Specify a start and end time for the account. The system process that deletes expired user accounts runs every 10 minutes. There might be a delay of some minutes before the account is purged. Even if the system time or date is moved ahead past the expiration time, the account could still be valid until the purge process runs. One-time user accounts are not deleted by the purge process; they are deleted immediately after the user exits.
End Time	
Company Name	(Optional) Specify the company with which the user is associated.
Host or Sponsor	(Optional) Specify the host or sponsor—for example, the person at your company who requested that you create the account.
One-time use	Select this option to limit the user to one log in. After one successful log in, the user's log in state is set to disabled, and the user receives an error message when attempting subsequent sign-ins. However, you can manually reset this option to allow the same user to log in again. If you do not select this option, the user account is subject to the specified start and end time for the account.
Enabled	Select this check box if it is not already selected. If the one-time use option has been implemented, this option is listed as Disabled after the user has logged in successfully. If a permanent or one-time user is logged in and you disable this option, the user is immediately logged out of the system and receives an error message.
Require user to change password	Select this option to force users to change their passwords at the next log in. <div>  If you force the user to change passwords, you must also enable the local authentication password management options. </div>
Custom Attributes	Select the custom attribute created and specify the value. Radius Return Attributes from the dictionaries is pre-populated to the Server Catalog of Local Auth server so that they are available under the custom attributes for a specific user.

Managing User Accounts

You use the Users page to list, modify, and delete local authentication server user accounts.

To manage a user account:

1. Select **Authentication > Auth. Servers**.
2. Click the link for the authentication server you want to manage.
3. Click the **Users** tab to display the user accounts table.

The user accounts table includes entries for the accounts that have been created. The Last Sign-in Statistic column shows the last successful sign-in date and time for each user, the user's IP address, and the agent or browser type and version.

Use the controls to search for users and manage user accounts:

1. To search for a specific user, enter a username in the Show users named box and click Update.

You can use an asterisk (*) as a wildcard, where * represents any number of zero or more characters. For example, to search for all usernames that contain the letters jo, enter *jo*. The search is case-sensitive. To display the entire list of accounts again, type * or delete the field's contents and click Update.

2. To limit the number of users displayed on the page, enter a number in the Show N users box and click Update.
3. To edit the user account configuration, click the link in the Username column to display the Update Local User Account page.
4. To terminate the user session and delete the account, select the box next to the user account record and click **Delete**.

Creating Administrator User Accounts

You use the Admin Users page to create accounts for local authentication server administrators. An administrator user can create, modify, and delete user accounts.

The admin users you create on the Admin Users page can view and manage all users that have been added to the local authentication server. In contrast, admin users you create by assigning the GUAM role capability can view and manage only the user accounts they created.

To create an administrator user account:

1. Select **Authentication > Auth. Servers**.
2. Click the link for the Guest Authentication Server you want to manage.
3. Click the **Admin Users** tab to display the configuration page.

4. Specify a username, select an authentication realm, and click **Add** to create the administrator user.
5. Save the configuration.

The screenshot shows the 'Admin Users' configuration page. At the top, the breadcrumb is 'Auth Servers > System Local'. Below it, the 'System Local' header is visible. A navigation bar contains 'Settings', 'Users', and 'Admin Users', with 'Admin Users' being the active tab. The main content area contains the following text:

A "User Admin" has some administrator capabilities on the device, including adding new users, changing passwords, and deleting existing users. You can delegate these abilities to User Admins per authentication server.

To create User Admins for server System Local, enter the user's username and the authentication realm used to authenticate the user. When this user signs in to the device, a "User Admin" link appears as a System menu. The user admin can click this link to manage users for the assigned authentication server.

Note: Please double-check to make sure the username is spelled correctly before adding the User Admin to the list.

An alternate option is to create a role for the "User Admin" which has the "Enable Guest User Account Management Rights" enabled. If using this role method, do not add a User Admin on this page. The advantage of the role option is that it will limit the "User Admin" to view only those accounts that they created.

Below the text, there is a form titled 'Add User Admin' and a list titled 'User Admins'. The 'Add User Admin' form includes a 'Username' input field, an 'Authentication Realm' dropdown menu (currently set to 'Users'), and two buttons: 'Add ->' and 'Remove'. The 'User Admins' list is currently empty.

Importing Users from CSV File

To bulk import users, or to add/change information about your users, you can use CSV Import feature.

Prepare a CSV for import. The mandatory required field's in the CSV is Username, password, you can choose to include additional user information if possible. View our available import fields and their associated formatting requirements in the CSV Import Fields table below.

1. Select **Auth Servers > System Local (Administrators, System Local, Guest Authentication) > Users**.
2. Click the **Browse** button to select the CSV file.
3. Enable Overwrite users to overwrite users with the same username if required. If the username exists in the local database before importing, enabling the overwrite option will delete the old entry and re-place with the newer entry present in the CSV file.

The CSV import allows you to import users in bulk with the following fields. Note that the header fields in your CSV must precisely match as shown in the CSV Fields column below in order for your import to be successful.

CSV Import Fields

CSV Fields	Description	Formatting Requirements	Character Limitations
Username	User name This is the mandatory field for a CSV import.	Username should be not present in the Local database.  If the Overwrite option is enabled the users with the same name in the local database will be overwritten.	Username should not contain "~" character.
Password	Password of the user		
This is the mandatory field for a CSV import.	Password should be based on the settings done in the password management/options for the specific local Auth server.	Password field should be in plaintext format.	

CSV Fields	Description	Formatting Requirements	Character Limitations
Full Name	Full Name (Optional field)	Only ASCII characters are accepted.	
Start Time	Start time (Optional field)	MM/DD/YYYY HH:MM:SS AM/PM	n/a
End Time	End time (Optional field)	MM/DD/YYYY HH:MM:SS AM/PM	n/a
Time Zone	Time Zone (Optional field)	To see the sample TimeZones in IPS:	
Navigate to System > Status > Overview > Date and Time.			
If the time zone is not mentioned in the CSV file, the default IPS timezone is considered.			
Use this format (including parentheses): (GMT+ 12:00) Alaska			
One Time Use	(Optional field)		
Disables the account after the next successful sign-in.	Only Binary values are accepted		
	"Disable- 0		
	"Enable- 1		
Enabled	(Optional field)		

CSV Fields	Description	Formatting Requirements	Character Limitations
Enable/Disable the user ID.	Only Binary values are accepted.		
	"Disable- 0		
	"Enable- 1		
Change Password at next sign in	(Optional field)		
Option to change the password for next sign-in	Only Binary values are accepted.		
	"Disable- 0		
	"Enable- 1		

Using Active Directory

This topic describes integration with the Microsoft® Windows® platform Active Directory™ service.

Microsoft Windows Platform Active Directory Service Overview

This section describes support for using IPS with the Active Directory AAA service.

Understanding Active Directory

Active Directory is a directory service used in Windows domain networks. It is included in most Windows server operating systems. Enterprise servers that run Active Directory are called domain controllers. An Active Directory domain controller authenticates and authorizes users and computers in a Windows domain network.

When you use Active Directory as the authentication and authorization service for your access management framework, users can sign in to IPS using the same username and password they use to access their Windows desktops. You can also use Active Directory group information in role mapping rules.

From 9.1R1 onwards, Active Directory Legacy Mode configuration will not be supported. If you have an existing Active Directory authentication server using Legacy Mode, first migrate to Standard Mode and then upgrade IPS. For the detailed migration procedure, refer [KB40430](#)

Active Directory Feature Support

Access management framework supports the following Active Directory features:

- Honors trust relationships in Active Directory and Windows NT environments.
- Supports Domain Local Groups, Domain Global Groups, and Universal Groups defined in the Active Directory forest.
- Supports use of Kerberos, NTLMv2, and NTLMv1 authentication protocols.
- Supports [user principal name \(UPN\)](#) format for usernames. The UPN should be able to pass validation against the domain joined by the IPS system either directly or by trust relationship. If a UPN is rejected it will not be retried against other domains. This support is available for Web login, IPS at Layer 3, and EAP-MS-CHAP v2.

Interoperability Requirements and Limitations

The following limitations apply to interoperability with Active Directory:

- The access management framework uses Active Directory security groups, not distribution groups. Security groups allow you to use one type of group for not only assigning rights and permissions, but also as a distribution list for e-mail.
- Each Active Directory configuration you create for the access management framework should use a different and unique machine account name.
- If the current Active Directory domain controller is not reachable, the user or machine authentication requests fail for a few seconds (less than 2 minutes) before attempting to authenticate users with another domain controller in the Active Directory domain.

- We do not support interoperability with Active Directory implementations that use the equal sign operator (=) in a group name, such as: "\=THIRD FLOOR GROUP". The access management framework authentication process involves search operations that use the equal sign operator (=) when parsing server catalogs to retrieve group names, usernames and domain names, as well as user_SID and domain_SID values. You might encounter unexpected behavior that can affect normal processing of authentication services if a group name configured on your Active Directory server includes an equal sign operator (=).
- Active Directory versions Windows 2008, Windows 2018 R2 and later use a dynamic port range. The default start port is 49152 and the default end port is 65535. Therefore, if there is a firewall between the Ivanti service and the Active Directory Service, you must increase the remote procedure call (RPC) port range on the firewall. See [Microsoft Knowledge Base article 929851](#).
- The Ivanti password management feature, which enables users to change their Active Directory passwords through the Ivanti service Web server, is not supported for users of trusted domains that do not trust the domain specified in the Ivanti Active Directory configuration.
- UPN format for user log in is not supported for MS-CHAP v2.

Understanding the Active Directory Standard Configuration

Active Directory standard configuration supports interoperability with any version of Active Directory, and is the required configuration mode to support authentication using MS-CHAP v2 with Windows 2008 R2 Active Directory Service. Machine authentication, for example, uses MS-CHAP v2.

Configuring Authentication and Authorization with Active Directory Service (Standard Mode)

To configure integration with Active Directory Service (standard mode):

1. Select **Authentication > Auth. Servers**.
2. Select **Active Directory / Windows NT** and click **New Server** to display the configuration page.
3. Select **Active Directory mode** and complete the configuration as described in table.
4. Save the configuration.

Settings	Guidelines
Mode	
	<p>Select one of the following modes:</p> <p>Active Directory—For recent versions of Windows Server. This table describes Active Directory mode.</p>
Base Configuration	
Name	Specify a name to identify the server within the system.
Domain	<p>Specify the NetBIOS domain name for the Active Directory domain. The system uses DNS to discover domain controllers in the Active Directory forest. It sends authentication requests to the domain controller at the closest site. Ensure that your DNS servers are configured to resolve the Active Directory domain controller fully qualified domain name (FQDN) and service (SRV) records.</p>
Kerberos Realm	Specify the FQDN of the Active Directory domain. For example, if “secure” is the domain name (NetBIOS name), then pulsesecure.net is the Kerberos realm name.
Domain Join Configuration	
Username	<p>Specify a username that has permission to join computers to the Active Directory domain. Use the “Delegate Control” workflow in Active Directory to assign the following user account permissions to the username or to a group to which the user belongs:</p> <ul style="list-style-type: none"> • Write • Write All Properties • Change Password • Reset Password • Validate Write to DNS hostname • Read and write DNS host attributes • Delete Computer Objects

Settings	Guidelines
	<ul style="list-style-type: none"> Create Computer Objects
Password	Specify the password for the special user.
Save Credentials	<p>If this setting is not enabled, the credentials entered will be destroyed after successfully joining the domain.</p> <p>This option is useful when managing clusters. For example, you might want to save the credentials for a cluster node you have yet to add. If you do not enable this option, you must manually enter the credentials when you add the new cluster node.</p>
Container Name	<p>Specify the container path in Active Directory in which to create the machine account. Changing this field triggers a domain rejoin action.</p> <p>The default is Computers, which is a standard container created during installation of the AD server. The AD Computers container is the default location for new computer accounts created in the domain.</p> <p>If desired, you may specify a different container or OU. To specify nested containers, use a forward slash (/) as the container separator. For example: outer OU/inner OU.</p> <hr/> <p> Do not use backslashes in the path. Using backslashes causes an Invalid DN Syntax error.</p> <hr/>
Computer Name	Specify the machine account name. The default computer name is derived from the license hardware in the following format: 0161MT2L00K2C0. We recommend the Computer Name string contain no more than 14 characters to avoid potential issues with the AD/NT server. Do not include the '\$' character.
Update Join Status / Reset Join	<p>The following colors are used to indicate status:</p> <p>Gray. The Domain Join action has not been attempted. This is the default status that appears when you are using the page to create a new Active Directory configuration.</p> <p>Yellow. Attempting to join the Active Directory domain. This is the default status that appears after saving configuration settings or when any domain join settings are changed in an existing configuration.</p> <p>Green. The attempt was successful. This status indicates that this server can now be used to authenticate users.</p> <p>Red. The attempt to join the Active Directory domain was not successful.</p>

Settings	Guidelines
	<p>Click Update Join to get the latest join status of nodes. If the status appears persistently red, click Reset Join to reinitiate the domain join process. The Reset Join action requires Active Directory administrator credentials.</p> <hr/> <p> For cluster nodes, you might need to click Update Join multiple times to obtain the latest join status of nodes.</p> <hr/> <p>Transient network issues might also cause the join status indicator to appear red. Before reinitiating the join process, ensure that it is not caused by network issues. Make sure your DNS servers can resolve queries to the Active Directory domain controller and that the Active Directory credentials are valid and have the appropriate permissions.</p>
Additional Options	

Settings	Guidelines
Authentication Protocol	<p>The system attempts authentication using the protocols you have enabled in the order shown on the configuration page. For example, if you have selected the check boxes for Kerberos and NTLMv2, the system sends the credentials to Kerberos. If Kerberos succeeds, the system does not send the credentials to NTLMv2. If Kerberos is not supported or fails, the system uses NTLMv2 as the next protocol in order.</p>
	<p>Kerberos. Select this option to enable the Kerberos authentication protocol. Kerberos is the most secure method and is required for Kerberos single sign-on authentication. Kerberos must be enabled if you plan to use Ivanti single sign-on or browser-based agentless single sign-on (SPNEGO).</p>
	<p>Enable NTLM protocol. Select this option to enable NTLM if you plan to use any of the following features:</p> <ul style="list-style-type: none"> Machine authentication using Ivanti Secure Access Client, or Windows native 802.1x supplicants. MS-CHAP-based authentication protocols for any 802.1x supplicants. User password management. Role mapping rules based on group membership. <p>If you enable NTLM, select one of the following versions:</p> <p>NTLMv2. This protocol is moderately secure. It is required for machine authentication and MS-CHAP v2 based 802.1x authentication protocols.</p> <p>NTLMv1. This protocol is comparatively less secure. It might be required for compatibility with existing legacy servers, MS-CHAP based servers, and MS-CHAP based 802.1x authentication protocols.</p>
Trusts	<p>Contact trusted domains. Select this option to contact domain controllers of trusted domains directly without proxying authentication requests and group membership checks through the domain controller.</p> <p>If this option is not selected:</p> <ul style="list-style-type: none"> Network contact with trusted domains is not permitted, but pass-through authentication using the primary domain is still permitted. Trusted domain user's group lookup for Kerberos SSO and SPNEGO authentication does not work even though user authentication succeeds. Trusted domain user's password-based authentication does not work.

Settings	Guidelines
	<p>Only groups from the domain in which this system is a member are available for use in role mapping when a group search is performed in the server catalog window.</p> <hr/> <p> If you want to restrict trusted domain users and computers (machine authentication) from logging in when this option is not selected, you can define a custom expression based on the ntdomain variable and use it in role mapping rules. For example, if IPS belongs to the domain named Corporate, you can define a custom expression as ntdomain=Corporate and use the custom expression in the role mapping rule of the realm.</p> <hr/>
SPNEGO Single Sign On	<p>Enable SPNEGO. Select this option to support SPNEGO SSO.</p> <hr/> <p>Keytab Upload. Select this option to use the controls to upload the SPNEGO keytab. The keytab must be generated on the Active Directory Service for the SPN. It must match the FQDN used to access this device.</p>
Machine account password change	<p>Enable periodic password change of machine account. Select this option to change the domain machine account password for this configuration.</p> <hr/> <p>Change machine password frequency. Specify a frequency in days. For example, every 30 days.</p>
Logical Auth Server Name	Specify a logical authentication server name.

You can troubleshoot the configurations using the Troubleshooting Tab for the respective server. You will be able to view this option on configuring the respective server. Using the troubleshooting option, you can validate:

- Domain Joint Status
- Authentication success status
- DNS Look-up for the respective servers
- Authentication Statistics

Using Kerberos SSO

Kerberos SSO Support Overview

Kerberos single sign-on (SSO) is a method of access control that allows a user to log in once to the client desktop without being prompted again for credentials.

The Kerberos SSO feature uses Kerberos authentication to automatically sign in users with the same credentials they used to access their Windows desktops. After you configure Kerberos SSO, the sign-in dialog box does not appear to users.

Requirements and Limitations

The following requirements and limitations apply to the Kerberos SSO implementation:

- The SSO feature requires a Windows NT Primary Domain Controller (PDC) or Active Directory for user authentication.
- The Kerberos SSO feature is not supported on Windows NT Server 4.0 or earlier
- The clocks on IPS and the Windows Active Directory authentication server must be synchronized to within 2 minutes of each other.
- The Active Directory controller must be deployed in front of IPS.
- The Windows endpoint computers must be joined to the same domain that IPS uses for authentication. Alternatively, make sure the Windows endpoint computers are joined to a domain that has a trust relationship with the domain that IPS uses for authentication.
- Users must sign into their endpoint computers in the domain of the Windows Active Directory authentication server or in a trusted domain.
- The realm Enable SSO option is visible only if the Windows Active Directory authentication server is used for authenticating users of the selected realm.

Enabling Kerberos SSO

To enable Kerberos SSO:

1. Select **Authentication > Auth. Servers**.
2. Select **New Active Directory / Windows NT** and click **New**.
3. Complete the configuration. Enable the Kerberos authentication protocol option.
4. Configure the realm:
 - Select **Administrators > Admin Realms or Users > User Realms**. Specify the realm that must use the Active Directory server to authenticate and authorize administrators and users.
 - Select **Administrators > Admin Realms > Select Realm > Authentication Policy > SSO** to ensure that the Enable SSO option is enabled (the default).

Understanding Multidomain User Authentication

This topic provides an overview of multi domain user authentication with Active Directory and Windows NT.

Multi-Domain User Authentication Overview

The access management framework allows for multidomain Active Directory and Windows NT authentication. The system authenticates users in the domain that you configure, users in child domains, and users in all domains trusted by the configured domain.

Users in the default domain can sign into the system using just their username, or the default domain and the username in the format default-domain\username.

When you enable trusted domain authentication, users in trusted or child domains can sign in using the name of the trusted or child domain and the username in the format trusted-domain\username. Note that enabling trusted domain authentication adds to the server response time.

Windows NT User Normalization

To support multidomain authentication, the access management framework uses “normalized” Windows NT credentials when it contacts an Active Directory or Windows NT4 domain controller for authentication. Normalized Windows NT credentials include both the domain name and the username: domain\username. Regardless of how the user signs in (either using just a username or using the domain\username format), the access management framework always processes the username in domain\username format.

When a user signs in using only their username, the access management framework normalizes their Windows NT credentials as default-domain\username. Authentication succeeds only if the user is a member of the default domain.

When a user signs in using the domain\username format, the access management framework attempts to authenticate the user as a member of the domain the user specifies. Authentication succeeds only if the user-specified domain is a trusted or child domain of the default domain. If the user specifies an invalid or untrusted domain, authentication fails.

Two variables, <NTUser> and <NTDomain>, allow you to individually refer to Windows NT domain and username values. The system populates these two variables with the Windows NT domain and username information.

In role mapping rules, when you specify **USER = someusername**, the system treats this rule semantically as **NTUser = someusername AND NTDomain = defaultdomain**.

Kerberos Support

We recommend you configure the access management framework to use the Kerberos authentication protocol with Windows domain controllers. When a user logs in to the system, the system performs Kerberos authentication and attempts to fetch the Kerberos realm name for the domain controller, as well as all child and trusted realms, using LDAP calls.

You can use Kerberos differently. You can specify the Kerberos realm name when configuring an Active Directory authentication server. We do not recommend this method for two reasons:

You cannot specify more than one realm name. The system cannot then authenticate against child or trusted realms of the realm you specify.

If you misspell the realm name, the system cannot authenticate users against the proper realm.

Windows NT4 Support

The access management framework does not support Kerberos-based authentication in Windows NT4 domain controllers. The system uses NTLM with a backend Windows NT4 domain controller.

Understanding Active Directory and Windows NT Group Information Support

This topic describes support for polling group information from Active Directory and Windows NT servers.

Active Directory Group Information Overview

The access management framework supports user group lookup in Domain Local, Domain Global, and Universal groups in the default domain, child domains, and all trusted domains. The system obtains group membership using one of three methods that have different capabilities:

- Group information in User's Security Context—Returns information about the user's Domain Global groups.
- Group information obtained using LDAP search calls—Returns information about the user's Domain Global groups and about the user's Universal groups if the access management framework queries the Global Catalog Server.
- Group information using native RPC calls—Returns information about the user's Domain Local Group.
- With respect to role-mapping rules, the system attempts group lookup in the following order:
 - Checks for all Domain Global groups using the user's security context.
 - Performs an LDAP query to determine the user's group membership.
 - Performs an RPC lookup to determine the user's Domain Local group membership.

Windows NT4 Group Information Overview

The access management framework supports group lookup in the Domain Local and Domain Global groups created in the default domain, as well as all child and other trusted domains. The system obtains group membership using:

- Domain Global group information from the user's security context.
- Domain Local information using RPC calls.

In the Windows NT4 environment, the system does not use LDAP-based search calls.

Importing and Exporting an Active Directory Mode Configuration

You can use the Maintenance > Import/Export > Import/Export users page to copy an Active Directory mode configuration from one system to another. If Active Directory credentials for joining a domain are not stored in the exported configuration, you must update the configuration to specify them.

Push configuration is not supported for Active Directory mode configurations.

XML Import/Export for the Active Directory mode configuration has limitations. An XML exported Active Directory configuration (standalone/cluster) can be imported to the same system from which it is exported. However, an XML exported Active Directory configuration from a standalone configuration cannot be imported into a cluster configuration. Similarly, an XML exported Active Directory configuration from a cluster cannot be imported into a standalone configuration.

It is not recommended that you import a configuration into a different system than the one from which the configuration was exported. Although the import operation will be successful, the importing system will join the AD domain with the same computer name as the exporting system. When this occurs, the Active Directory disconnects the earlier join from the exporting system.

To work around this, modify the value of the computer-name parameter in the XML file to be unique and then import it to another system. In cluster configurations, in addition to modifying the computer-name parameter, also modify the node parameter for each cluster member to match with the importing cluster node names.

Here are the parameters you must change before importing the XML configuration file of Active Directory:

```
<nodenames>
<node>clusternode1</node>
<computer-name>computer1</computer-name>
</nodenames>
<nodenames>
<node>clusternode2</node>
<computer-name>computer2</computer-name>
```

</nodenames>

You must specify the clear text password within <password-cleartext> </password-cleartext> tags, in place of <user-password-encrypted> </user-password-encrypted> tags, before you perform an XML Import of an Active Directory mode configuration.

Using the Anonymous Server

This topic describes integration with the anonymous server.

Anonymous Server Overview

This section describes support for using IPS with the anonymous server.

Understanding the Anonymous Server

The anonymous server is a local authentication server that allows any user to access the system without providing a username and password.

Instead, when a user enters the URL of a sign-in page that is configured to authenticate against an anonymous server, the IPS access management framework bypasses the standard sign-in page and immediately displays the welcome page to the user.

Anonymous Server Feature Support

IPS access management framework supports the following anonymous server features:

- Enables guest access without username or password
- Supports Host Checker scans before allowing a guest device to connect to the network
- Supports firewall enforcement roles and policies to limit the resources available to the guest user

Interoperability Requirements and Limitations

The following limitations apply to the anonymous server configuration and logging:

- You can add only one anonymous server configuration.
- You cannot create an administrator realm that uses the anonymous server. Anonymous administration is not allowed.
- During configuration, you must choose the anonymous server as both the authentication server and the directory or attribute server in the Users > User Realms > General tab.
- For security reasons, you might want to limit the number of users who sign in through an anonymous server at any given time. To do this, use the option on the Users > User Realms > [Realm] > Authentication Policy > Limits tab (where [Realm] is the realm that is configured to use the anonymous server to authenticate users).

Configuring Authentication with the Anonymous Server

To configure authentication with the anonymous server:

1. Select **Authentication > Auth. Servers**.
2. Select **Anonymous Server** and click **New Server** to display the configuration page.
3. Save the configuration.

Monitoring Anonymous User Sessions

The purpose of the anonymous server is to enable unauthenticated access. Therefore, the system does not maintain session tables, and the Anonymous Server configuration page does not have a corresponding Users tab. The system does maintain user access logs for anonymous access. The username is recorded in the user access log as "AnonUser1234". If the user is logging in using the agentless access method, the user access log records the host's IP address. You can view the User Access Log file by navigating to **System > Log/Monitoring**.

Using the Certificate Server

This topic describes integration with the certificate server.

Certificate Server Overview

This section describes support for using IPS with the certificate server.

Understanding the Certificate Server

The certificate server is a local server that allows user authentication based on the digital certificate presented by the user without any other user credentials.

When you use a certificate server, the user experience is similar to anonymous authentication. If the certificate is secured through a hardware or a software token or through a password, the certificate server authentication is very useful. The certificate contains the full distinguished name (DN) and the system extracts the values from the DN and uses it for role mapping rules, authentication policies, and role restrictions.

Feature Support

The Ivanti Policy Secure(IPS) access management framework supports the following certificate server features:

- Certificate directory services to retrieve user attributes in role mapping rules, authentication policies, and role restrictions.
- Load CA-created certificates on the system.
- Load multiple certificates from different CAs for use with different authentication realms.

Interoperability Requirements and Limitations

If you choose a certificate attribute with more than one value, the system uses the first matched value. For example, if you enter <certDN.OU> and the user has two values for the attribute (ou=management, ou=sales), the system uses the "management" value.

To use all values, add the SEP attribute to the variable. For example, if you enter <certDN.OUT SEP=":"> the system uses "management:sales".

Configuring Authentication with the Certificate Server

To configure authentication with the certificate server:

1. Select **Authentication > Auth. Servers**.
2. Select **Certificate Server** and click **New Server** to display the configuration page.
3. Complete the configuration as described in table.
4. Save the configuration.

Auth Servers > New Certificate Server

New Certificate Server

*Name: Label to r

User Name Template: Template

The template can contain textual characters as well as variables for custom expressions and policy conditions. All of the certificate variables are listed below.

Examples:

- <certDN.CN> First CN from the subject DN
- <certAttr.serialNumber> Certificate serial number
- <certAttr.altName.xxx> Where xxx can be:
 - Email The Email alternate name
 - UPN The Principal Name alternate name
 - ... etc
- <certDNText> The complete subject DN
- cert-<certDN.CN> The text "cert-" followed by the first CN from the subject DN

✔ User Record Synchronization

☐ Enable User Record Synchronization

Logical Auth Server Name:

* indicates required field

Settings	Guidelines
Name	Specify a name to identify the server within the system.
User Name Template	<p>Specify a username template. Specify how the system should construct a username. You may use any combination of certificate variables contained in angle brackets and plain text.</p> <hr/> <p> This value populates the <USER> and <USERNAME> session variables for use throughout the rest of the system configuration.</p> <hr/>
Logical Auth Server Name	Specify a logical authentication server name.

Displaying the User Accounts Table

To display user accounts:

1. Select **Authentication > Auth. Servers**.
2. Click the link for the authentication server you want to manage.
3. Click the **Users** tab to display the user accounts table.

The user accounts table includes entries for the accounts that have been created. The Last Sign-in Statistic column shows the last successful sign-in date and time for each user, the user's IP address, and the agent or browser type and version.

4. Use the controls to search for users and manage user accounts:
 - To search for a specific user, enter a username in the Show users named box and click **Update**.

You can use an asterisk (*) as a wildcard, where * represents any number of zero or more characters. For example, to search for all usernames that contain the letters jo, enter *jo*. The search is case-sensitive. To display the entire list of accounts again, type * or delete the field's contents and click **Update**.

- To limit the number of users displayed on the page, enter a number in the Show N users box and click **Update**.
- To terminate the user session and delete the account, select the check box next to the user account record and click **Delete**.

Using an LDAP Server

This topic describes integration with the LDAP server.

LDAP Server Overview

This section describes support for using IPS with the LDAP server.

Understanding LDAP Server

Lightweight Directory Access Protocol (LDAP) facilitates the access of online directory services. The Internet Engineering Task Force (IETF) designed and specified LDAP as a better way to make use of X.500 directories, having found the original Directory Access Protocol (DAP) too complex for average Internet clients to use. LDAP is a relatively simple protocol for updating and searching directories running over TCP/IP.

LDAP directory consists of a collection of attributes with a name, known as a distinguished name (DN). Each of the entry's attributes, known as a relative distinguished name (RDN), has a type and one or more values. The types are typically mnemonic strings, such as CN for common name. The valid values for each field depend on the types.

The full DN is constructed by stringing together RDNs from most specific to least specific, separated by commas, as shown in the following example:

cn=Bob_Employee, ou= account_mgr, o=sales, dc=Acme,dc=com.

LDAP Feature Support

Access management framework supports the following LDAP features:

- LDAP directory services to retrieve user attributes and group membership in role mapping rules
- Encrypted connections to the LDAP server using LDAP over SSL (LDAPS) or Start Transport Layer Security (TLS)
- Password management feature enabling users who access an LDAP server to manage their passwords using the policies defined on the LDAP server
- Fine-grained password policy (FGP) for Active Directory 2008

Interoperability Requirements and Limitations

The following limitations apply to interoperability with LDAP:

- By default, challenge response protocols are disabled for LDAP servers. Use these protocols only with noninteractive devices (for example, phones), as password management is not possible if these protocols are used for authentication.

- To use the CHAP, EAP-MD5-Challenge, MS-CHAP-V1, and MS-CHAP-V2 protocols, the LDAP server must store the user's password in clear text.
- Backup LDAP servers must be the same version as the primary LDAP server. Also, we recommend that you specify the IP address of a backup LDAP server instead of its hostname, which might accelerate failover processing by eliminating the need to resolve the hostname to an IP address.

Configuring Authentication with an LDAP Server

To configure authentication with an LDAP server:

1. Select **Authentication > Auth. Servers**.
2. Select **LDAP Server** and click **New Server** to display the configuration page.
3. Complete the configuration as described in table.
4. Save the configuration.

Auth Servers > New LDAP Server

New LDAP Server

*Name: Label to reference this server.

*LDAP Server: Name or IPv4/IPv6 address

*LDAP Port:

Backup LDAP Server1: Name or IPv4/IPv6 address

Backup LDAP Port1:

Backup LDAP Server2: Name or IPv4/IPv6 address

Backup LDAP Port2:

LDAP Server Type:

Connection: ☒ Unencrypted ☐ LDAPS ☐ Start TLS

Connection Timeout: Seconds to wait for connection to LDAP server

Search Timeout: Seconds to wait for search results, excluding connection time

[Test Connection](#)

✓ **Authentication required**

In order to use Password Management, you may need to select the 'Authentication required to search LDAP' checkbox below and enter your LDAP administrator DN and password.

☐ Authentication required to search LDAP

Admin DN:

Password:

Backup Admin DN:

Backup Admin Password:

✓ **Finding user entries**

Specify how to find a user entry

Base DN: example: dc=sales,dc=com

*Filter: example: cn=*USER*

✓ **Remove Domain from Windows user names**

If users authenticate using Windows user names containing domain prefixes (for example: CORP\joe), it may be necessary to remove the domain prefix in order for authentication to succeed. If you choose this option, the <NTDOMAIN> variable is set to the domain name that was removed from the user name.

☐ Strip domain from Windows user names

✓ **Enable Challenge Response open protocols**

Because LDAP authentication servers generally do not support these protocols natively and the user's password is encrypted, it is necessary to bind as the administrator to authenticate a user. This prevents the authentication server from performing account and password management, which is used to determine things like disabled accounts or expired passwords. Enable these protocols only if your LDAP store is being used solely for non-interactive devices such as telephones that do not require account or password management functionality.

☐ Enable Challenge-Response open protocols

✓ **Determining group membership**

If group membership is NOT reflected as attributes of a user's entry, specify how to find a group's entries. Note that these are default settings that you can override on a per-group basis in the Server Catalog.

Base DN: example: dc=sales,dc=com

Filter: example: cn=<GROUPNAME>

Member Attribute: Attribute used to identify members of a static group or groups to which a member belongs

Query Attribute: Attribute used to determine members of a dynamic group

Nested Group Level:

Nested Group Search: ☒ Nested groups in Server Catalog Faster, but less flexible
☐ Search all nested groups Slower, but more flexible

[Save Changes](#) [Reset](#)

Settings	Guidelines
Name	Specify a name to identify the server within the system.
Enable Domain Name (enabled)	Select this option to fetch a list of servers from the DNS server.
	Domain Name When you Enable Domain Name, specify the LDAP Domain name that can be mapped to domain controllers by DNS service.

Settings	Guidelines
Enable Domain Name (disabled)	Clear this option if you want to manually enter all the domain controllers host names.
	<p>LDAP Server: Specify the LDAP server name or the IPv4/IPv6 address.</p> <p>Backup LDAP Server1: (Optional) Specify the parameters for backup LDAP server1. Enter server name or the IPv4/IPv6 address.</p> <p>The specified backup LDAP server is used for failover processing. The authentication request is first routed to the primary LDAP server, and then to the specified backup servers if the primary server is unreachable.</p>
	Backup LDAP Port1: Specify the parameters for backup LDAP port1.
	Backup LDAP Server2: (Optional) Specify the parameters for backup LDAP server2. Enter server name or the IPv4/IPv6 address.
LDAP Port	Specify the LDAP port for the LDAP server. Default port number: 389 (unencrypted connection) Default port number: 636 (SSL connection)
LDAP Server Type	Select the backend LDAP server type from the following choices: Generic Active Directory Profiler (Policy Secure only)
Connection	<p>Select one of the following options for the connection to the LDAP server:</p> <ul style="list-style-type: none"> • Unencrypted– The device sends the username and password to the LDAP Directory Service in clear text. • LDAPS– The device encrypts the data in the LDAP authentication session using the Secure Socket Layer (SSL) protocol before sending it to the LDAP Directory Service. • Start TLS– The device allows both secure and plain requests against an LDAP server on a single connection.

Settings	Guidelines
	<ul style="list-style-type: none"> - If you select LDAPS or Start TLS, the Validate Certificate option is displayed for the configured LDAP server(s) and its referral servers. Select this option if the SSL connection uses digital certificate security. - If you enable validation for the referral servers, make sure your network DNS supports reverse lookup zone. - If you want to verify the server certificates, the root CA and Intermediate CAs must be imported as trusted CAs.
Connection Timeout (seconds)	Specify the time to wait for connection to the primary LDAP server, and then to each backup LDAP server. Default: 15 seconds
Search Timeout (seconds)	Specify the time to wait for search results from a connected LDAP server.
Test Connection	<p>(Optional) To verify the connection between Ivanti Secure Access Client and LDAP servers, click the Test Connection button.</p> <p> We recommend using the Test Connection function only after saving changes on the LDAP Server Configuration page.</p>
Authentication required?	
Authentication required to search LDAP	<p>Select this option to require authentication when performing search or password management operations.</p> <ul style="list-style-type: none"> - If you use Active Directory, you must select the Authentication required to search LDAP check box and provide the full DN and password of an account that can reach Active Directory. - You can enable password management on any LDAP server. - This feature enables users who authenticate through an LDAP server to manage their passwords through the system using the policies defined on the LDAP server. To enable password management on any LDAP server, you must provide primary and backup administrator accounts (with write privileges to the directory) for the administrator DN and backup administrator DN.

Settings	Guidelines
Admin DN	Specify the administrator DN for queries to the LDAP directory.
Password	Specify the password for the LDAP server.
Backup Admin DN	Specify the backup administrator DN for queries to the LDAP directory, as a fallback when primary Admin DN fails (due to account expiration). The interaction with LDAP directory stops when both primary and backup administrator accounts fail.
Backup Admin Password	Specify the backup administrator password for the LDAP server.
Finding user entries	
Base DN	Specify the base DN under which the users are located. For example, dc=sales,dc=acme, dc=com.
Filter	Specify a unique variable that can be used to do a fine search in the tree. For example, samAccountname= <username> or cn= <username>. Include <username> in the filter to use the username entered on the sign-in page for the search. Specify a filter that returns 0 or 1 user DN's per user; the device uses the first DN returned if more than 1 DN is returned.
Remove Domain from Windows users names?	
Strip domain from Windows username	Select this option to pass the username without the domain name to the LDAP server.
Enable Challenge-Response open protocols?	
Enable Challenge-Response open protocols	Select this option if you want to use a challenge-response protocol for authentication. By default, these protocols are disabled for LDAP servers because account management is not possible.

Settings	Guidelines
Determining group membership	
Base DN	Specify the base DN to search for user groups.
Filter	Specify a unique variable which can be used to do a fine search in the tree. For example, samAccountname= <username> or cn= <GROUPNAME>.
Member Attribute	Specify all the members of a static group. For example, member or uniquemember.
Reverse group search	Select this option to start the search from the member instead of the group. This option is available only for Active Directory server types.
Query Attribute	Specify an LDAP query that returns the members of a dynamic group. For example, memberURL.
Nested Group Level	Specify how many levels within a group to search for the user. The higher the number, the longer the query time, so we recommend that you specify to perform the search no more than two levels deep.
Nested Group Search	Select one of the following options: Nested groups in Server Catalog—This option is faster because it can search within the implicit boundaries of the nested group. Search all nested groups—With this option, the device searches the Server Catalog first. If the device finds no match in the catalog, then it queries LDAP to determine if a group member is a subgroup.

Displaying the User Accounts Table

To display user accounts:

1. Select **Authentication > Auth. Servers**.
2. Click the link for the authentication server you want to manage.

3. Click the **Users** tab to display the user accounts table.

The user accounts table includes entries for the accounts that have been created. The Last Sign-in Statistic column shows the last successful sign-in date and time for each user, the user's IP address, and the agent or browser type and version.

4. Use the controls to search for users and manage user accounts:

- To search for a specific user, enter a username in the Show users named box and click **Update**.

You can use an asterisk (*) as a wildcard, where * represents any number of zero or more characters. For example, to search for all usernames that contain the letters jo, enter *jo*. The search is case-sensitive. To display the entire list of accounts again, type * or delete the field's contents and click **Update**.

- To limit the number of users displayed on the page, enter a number in the Show N users box and click **Update**.
- To terminate the user session and delete the account, select the check box next to the user account record and click **Delete**.

Using the LDAP Password Management Feature

This topic describes support and limitations for LDAP password management.

LDAP Password Management Feature Overview

The password management feature enables users who access an LDAP server to manage their passwords through the access management framework using the policies defined on the LDAP server. For example, if a user tries to sign in to the system with an LDAP password that is about to expire, the system notices the user through the interface, and then passes the user's response back to the LDAP server without requiring the user to sign in to the LDAP server separately.

Users, administrators, and help desk administrators who work in environments where passwords have set expiration times may find the password management feature very helpful. If users are not informed that their passwords are about to expire, they can change them themselves through the system rather than call the help desk.

Once this feature is enabled, the system performs a series of queries to determine user account information, such as when the user's password was last set, whether the account is expired, and so on. The access management framework does this by using its internal LDAP or Samba client. Many servers, such as Microsoft Active Directory, offer an Administrative Console to configure account and password options.

LDAP-based password management works with only three types of LDAP servers:

- Microsoft Active Directory. For Active Directory, password policy attributes can be configured in the user entry container level or any organization level above the user container. If these attributes are configured at multiple levels, the level closest to the user node takes precedence. The password management feature is not supported on the Active Directory Global Catalog because password policy attributes are not fully populated in the Active Directory Global Catalog.
- For Active Directory 2008, the access management framework supports the Fine Grained Password Policy (FGP) configured in the AD user container.

LDAP-based password management does not work on generic LDAP servers such as OpenLDAP.

The system relies on the back-end server to pinpoint the cause of error when a password change operation fails. However, although LDAP servers may report errors accurately to human operators, they do not always do so when communicating programmatically to systems. Therefore, reported errors might be generic or cryptic.

The system does not support customized password policies.

Enabling LDAP Password Management

To enable password management, you must first create an instance of the LDAP server. Next, you associate the LDAP server with the applicable realms. Finally, you select the enable password management feature at the realm level.

LDAP Password Management Support

The access management framework supports password management with the following LDAP directories:

- Microsoft Active Directory/Windows NT
- Generic LDAP directories, such as IBM Secure Directory and OpenLDAP

The below table describes supported password management functions, their corresponding function names in the individual LDAP directories, and any additional relevant details. These functions must be set through the LDAP server itself before the system can pass the corresponding messages, functions, and restrictions to end users.

The Active Directory attribute names shown are specific to the Domain Security Policy object. Similar attributes for the corresponding functions are used for the Active Directory 2008 Fine-Grained Password Policy. Refer to Microsoft documentation for details.

When authenticating against a generic LDAP server, such as IBM Secure Directory, the system supports only authentication and allowing users to change their passwords. Password management functions are not supported when the CHAP family protocols are used for authentication. All functions are available when the JUAC protocol is used for authentication.

Function	Active Directory	eDirectory	Generic
Authenticate user	unicodePwd	userPassword	userPassword
Allow user to change password if enabled	Server tells us in bind response (uses ntSecurityDescriptor)	If passwordAllowChange == TRUE	Yes
Log out user after password change	Yes	Yes	Yes
Force password change at next log in	If pwdLastSet == 0	If pwdMustChange == TRUE	-
Expired password notification	userAccountControl == 0x80000	Check date/time value	-
Password expiration notification (in X days/hours)	if pwdLastSet - now() < maxPwdAge - 14 days (Read from domain attributes) (The system displays warning if less than 14 days)	If now() - passwordExpirationTime < 14 days (The system displays warning if less than 14 days)	-

Function	Active Directory	eDirectory	Generic
Disallow authentication if "account disabled/locked"	userAccountControl == 0x2 (Disabled) accountExpires userAccountControl == 0x10 (Locked) lockoutTime	Bind ErrorCode: 53 "Account Expired" Bind ErrorCode: 53 "Login Lockout"	-
Honor "password history"	Server tells us in bind response	Server tells us in bind response	-
Enforce "minimum password length"	If set, the system displays message telling user minPwdLength	If set, the system displays message telling user passwordMinimumLength	-
Disallow user from changing password too soon	If pwdLastSet - now() < minPwdAge, then we disallow	Server tells us in bind response	-
Honor "password complexity"	If pwdProperties == 0x1, then enabled. Complexity means the new password does not contain username, first or last name, and must contain characters from 3 of the following 4 categories: English uppercase, English lowercase, Digits, and Non-alphabetic characters (ex. !, \$, %)	Server tells us in bind response	-

Note the following expected behavior:

- The system displays a warning about password expiration only if the password is scheduled to expire in 14 days or less. The system displays the message during each sign-in attempt. The warning message contains the remaining number of days, hours, and minutes that the user has to change the password before it expires on the server. The default value is 14 days, but you can change it on the password configuration page of the admin console.

LDAP Password Management for Windows AD Versions

The access management framework supports password management with the following Windows servers:

- Microsoft Active Directory 2008
- Microsoft Active Directory 2003
- Windows NT 4.0

Table describes supported password management functions. These functions are not supported for a layer 2 connection when CHAP, MS-CHAP, or PAP are used as authentication protocols.

Function	Active Directory	Active Directory 2003	Active Directory 2008 FGP	Windows NT
Authenticate user	Yes	Yes	Yes	Yes
Allow user to change password if licensed and if enabled	Yes	Yes	Yes	Yes
Log out user after password change	Yes	Yes	Yes	Yes
Force password change at next log in	Yes	Yes	Yes	Yes
Password expired notification	Yes	Yes	Yes	Yes
Account disabled	Yes	Yes	Yes	Yes
Account expired	Yes	Yes	Yes	Yes

Note the following expected behavior:

- Changes on the Active Directory domain security policy can take 5 minutes or longer to propagate among Active Directory domain controllers. Additionally, this information does not propagate to the domain controller on which it was originally configured for the same time period. This issue is a limitation of Active Directory.
- When changing passwords in Active Directory using LDAP, the system automatically switches to LDAPS, even if LDAPS is not the configured LDAP method. To support LDAPS on the Active Directory server, you must install a valid SSL certificate into the server's personal certificate store. The certificate must be signed by a trusted CA, and the CN in the certificate's Subject field must contain the exact hostname of the Active Directory server, (for example: adsrv1.company.com). To install the certificate, select the Certificates Snap-In in the Microsoft Management Console (MMC).
- The Account Expires option in the User Account Properties tab only changes when the account expires, not when the password expires. Microsoft Active Directory calculates the password expiration using the Maximum Password Age and Password Last Set values retrieved from the User object and Fine-Grained Password Policy objects or the Domain Security Policy LDAP objects.
- The system displays a warning about password expiration only if the password is scheduled to expire in 14 days or less. The system displays the message during each sign-in attempt. The warning message contains the remaining number of days, hours, and minutes that the user has to change the password before it expires on the server. The default value is 14 days, but you can change it on the password configuration page of the admin console.

Troubleshooting LDAP Password Management

When you troubleshoot, provide any pertinent system logs, server logs, configuration information, and a TCP trace from the system. If you are using LDAPS, switch to the "Unencrypted" LDAP option LDAP server configuration while taking the LDAP TCP traces.

Using the MAC Address Authentication Server

This topic describes how to use the MAC address authentication server.

MAC Address Authentication Server Overview

This section describes IPS MAC address authentication solution.

Understanding MAC Address Authentication

MAC address authentication is port-based security typically deployed at the edge of the network to enable secure access for non-user devices, such as IP phones, printers, and network attached storage devices. The Ivanti MAC address authentication solution uses IPS 802.1x framework. When a device connects to a switch, the switch forwards the MAC address as the log in credential to IPS RADIUS server. With MAC-based authentication, the MAC address serves as both the username and the password. The RADIUS server consults the authentication server and sends back a RADIUS return attribute based on authentication results.

BEST PRACTICE: MAC-based authentication is not as secure as agent access or agentless access authentication. MAC addresses are not generally guarded as secrets, so an attacker can spoof a MAC address and impersonate a device to gain network access. To reduce risk of an exploit, create a special VLAN for each device type.

MAC Address Authentication Server Feature Support

The MAC address authentication server is a local authentication server that supports both a local database of records and integration with LDAP servers. You can add entries manually or by reference to LDAP servers. The address table for each local MAC address authentication server is limited to 500 entries. We recommend you use LDAP for large-scale projects.

Interoperability Requirements and Limitations

Integration with an LDAP server requires the LDAP server to communicate with IPS internal interface.

MAC Address Authentication Framework Configuration Overview

The MAC address authentication framework is similar to the user access management framework. It involves configuration of a MAC address authentication server, MAC address realm, and roles.

To implement the MAC address authentication framework:

1. If necessary, use the Authentication Protocols Sets page to add the protocols that your Ethernet switches use for MAC authentication to IPS 802.1x protocol set. Select Authentication > Signing In > Authentication Protocols Sets.

The HP and Cisco switches can use CHAP and EAP-MD5-Challenge protocols for MAC address authentication with the username (the MAC address) as the clear text password. By default, the Nortel switch uses PAP, with a password in the format .<MAC Address>. We recommend using PAP with the Nortel switch.

2. Create LDAP server configurations for the external LDAP servers used to maintain MAC address records.
3. Create a MAC address authentication server.
4. Create Users.

Radius Return Attributes from the dictionaries is pre-populated to the Server Catalog of MAC Auth server so that they are available under the custom attributes for a specific user.

5. Create roles for agentless access.
6. Create a MAC address authentication realm that uses the MAC address authentication server and role mapping rules that sort MAC address authentication requests into roles according to your security policy design.

802.1x Framework Configuration Overview

The MAC address authentication solution uses Ivanti Policy Secure 802.1x framework.

To implement the 802.1x framework:

- Complete the Location Group configuration.
- Complete the RADIUS Client configuration.
- Complete the RADIUS Return Attributes Policy configuration.

Ethernet Switch MAC Address Authentication Configuration Overview

The MAC address solution depends on the Ethernet switch configuration.

To configure MAC address authentication on the Ethernet switch:

- Configure the switch as an 802.1x authenticator and enable MAC RADIUS protocols.
- Configure RADIUS client communication with IPS RADIUS server.
- Configure Ethernet switching options and VLANs to provision VLANs for non-user devices.

Configuring the EX Series Switch

The nonsupplicant devices, such as VoIP phones, connect to the network through an EX Series switch using MAC RADIUS authentication. You configure the following EX Series features to support this solution:

- Configure the switch as an 802.1x authenticator and enable MAC RADIUS protocols.
- Configure RADIUS client communication with IPS RADIUS server.
- Configure Ethernet switching options and VLANs to provision a VLAN for VoIP phones.

The following example shows commands that configure the ge-0/1/0.0 and ge-0/1/1.0 interfaces as 802.1x authenticators, enable MAC RADIUS protocols, and create a reference to the authentication profile used for integration with IPS RADIUS server:

```
set protocols dot1x authenticator authentication-profile-name
pulsesecure-access-profile
set protocols dot1x authenticator interface ge-0/1/0.0 supplicant
multiple
set protocols dot1x authenticator interface ge-0/1/0.0 transmit-
period 15
set protocols dot1x authenticator interface ge-0/1/0.0 mac-radius
set protocols dot1x authenticator interface ge-0/1/0.0 maximum-
requests 2
set protocols dot1x authenticator interface ge-0/1/0.0 server-fail
vlan-name enterprise
set protocols dot1x authenticator interface ge-0/1/1.0 supplicant
multiple
set protocols dot1x authenticator interface ge-0/1/1.0 quiet-period 5
set protocols dot1x authenticator interface ge-0/1/1.0 transmit-
period 15
set protocols dot1x authenticator interface ge-0/1/1.0 mac-radius
```

```
set protocols dot1x authenticator interface ge-0/1/1.0 supplicant-  
timeout 15  
set protocols dot1x authenticator interface ge-0/1/1.0 maximum-  
requests 2  
set protocols dot1x authenticator interface ge-0/1/1.0 guest-vlan  
guest  
set protocols dot1x authenticator interface ge-0/1/1.0 server-reject-  
vlan vlan-name guest  
set protocols dot1x authenticator interface ge-0/1/1.0 server-fail  
vlan-name enterprise
```

The following example shows commands that configure the access profile for IPS RADIUS server and the RADIUS client connection to it:

```
set access radius-server 10.0.1.5 port 1812  
set access radius-server 10.0.1.5 secret  
"$9$JLZHmzF/t0I69Icrv7N24aZikmfT3/C"  
set access radius-server 10.0.1.5 timeout 5  
set access radius-server 10.0.1.5 retry 3  
set access profile pulsesecure-access-profile authentication-order  
radius  
set access profile pulsesecure-access-profile radius authentication-  
server 10.0.1.5  
set access profile pulsesecure-access-profile radius accounting-  
server 10.0.1.5  
set access profile pulsesecure-access-profile accounting order radius
```

The following example shows commands that configure the Ethernet switching options and VLAN used for VoIP phones:

```
set ethernet-switching-options voip interface ge-0/0/10.0 vlan VoIP_  
Phone  
set ethernet-switching-options voip interface ge-0/0/11.0 vlan VoIP_  
Phone  
set ethernet-switching-options voip interface ge-0/0/8.0 vlan VoIP_  
Phone  
set ethernet-switching-options voip interface ge-0/0/9.0 vlan VoIP_  
Phone  
set ethernet-switching-options voip interface ge-0/0/6.0 vlan VoIP_  
Phone  
set ethernet-switching-options voip interface ge-0/0/7.0 vlan VoIP_  
Phone
```

```
set ethernet-switching-options voip interface ge-0/0/4.0 vlan VoIP_
Phone
set ethernet-switching-options voip interface ge-0/0/5.0 vlan VoIP_
Phone
set ethernet-switching-options voip interface ge-0/1/0.0 vlan VoIP_
Phone
set ethernet-switching-options voip interface ge-0/1/1.0 vlan VoIP_
Phone
set vlans VoIP_Phone description "VoIP Phones"
set vlans VoIP_Phone vlan-id 5
```

The following example shows the complete configuration hierarchy for the Ethernet switch configuration:

```
system {
  host-name Demo_EX;

  vlan-id 4;  
  interface {  
    ge-0/0/10.0;  
    ge-0/0/11.0;  
  }  
}  
  
poe {  
  interface all;  
}
```

In addition to the configuration for the MAC authentication solution shown above, you can also configure the switch to send data (SNMP traps) to the Beacon Endpoint Profiler for use in profiling. The following example commands configure SNMP traps to the Beacon Endpoint Profiler. The Beacon Endpoint Profiler can use the traps to build profile entries:

```
set snmp description EX4200-VOIP-Switch  
set snmp contact ex-admin@company.com  
set snmp view jweb-view-all oid .1 include  
set snmp community public view jweb-view-all  
set snmp community public authorization read-only  
set snmp community public clients  
<BeaconEndpointProfilerIPAddressOrSubnet>  
set snmp trap-group Beacon version v2  
set snmp trap-group Beacon categories link  
set snmp trap-group Beacon targets <BeaconEndpointProfilerIPAddress>
```

To verify that the Beacon Endpoint Profiler can read the EX Series MIB, run the following command from the Beacon Endpoint Profiler command line:

```
snmpwalk -v 2c -c public <EXseriesIPAddress>
```

Using a RADIUS Server

This topic describes integration with the RADIUS server.

RADIUS Server Overview

This section describes support for using an external RADIUS server.

Understanding RADIUS Server

A Remote Authentication Dial-In User Service (RADIUS) server is a type of server that allows you to centralize authentication and accounting for users.

The following authentication schemes are supported:

- Access-Request—The user enters the username and password to request access to RADIUS server.
- Access-Accept—The user is authenticated.
- Access-Reject—The user is not authenticated and is prompted to reenter the username and password, or access is denied.
- Access-Challenge—A challenge is issued by the RADIUS server. The challenge collects additional data from the user.

Feature Support

Access management framework supports the following RADIUS features:

- RADIUS authentication.
- RADIUS attributes that can be used in role mapping.
- RADIUS directory services to retrieve user attributes in role-mapping rules.
- RADIUS accounting to track the services and the network resources used.
- RADIUS proxy to configure your external RADIUS server as an inner or outer proxy target. When you specify RADIUS proxy, some fields in the RADIUS server configuration page are not

applicable. This feature is supported only on IPS.

- RADIUS Disconnect messages.

Using Challenge Expressions

The access management framework supports the RSA Authentication Manager using the RADIUS protocol and a SecurID token (available from Security Dynamics). If you use SecurID to authenticate users, they must supply a user ID and the concatenation of a PIN and a token value.

When you define a RADIUS server, the access management framework allows administrators to use hard-coded (default) challenge expressions that support Defender 4.0 and some RADIUS server implementations (such as Steel-Belted RADIUS and RSA RADIUS) or to enter custom challenge expressions that allow the system to work with many different RADIUS implementations and new versions of the RADIUS server, such as Defender 5.0. The system looks for the response in the Access-Challenge packet from the server and issues an appropriate Next Token, New PIN, or Generic Passcode challenge to the user.

Using CASQUE Authentication

CASQUE authentication uses a token-based challenge/response authentication mechanism employing a CASQUE player installed on the client system. Once configured with CASQUE authentication, the RADIUS server issues a challenge with a response matching the custom challenge expression (:([0-9a-zA-Z/+ =] +):). The system then generates an intermediate page that automatically launches the CASQUE player installed on the user's system.

PassGo Defender

If you are using a PassGo Defender RADIUS server, the user sign-in process is as follows:

1. The user is prompted for and enters a username and password.
2. The username and encrypted password are sent over the network to the RADIUS server.
3. The RADIUS server sends a unique challenge string to the system. The system displays this challenge string to the user.
4. The user enters the challenge string in a Defender token and the token generates a response string.
5. The user enters the response string on the system and clicks **Sign In**.

Using RADIUS Attributes

Table describes the RADIUS attributes that are supported in RADIUS role-mapping.

Attribute	Description
ARAP-Challenge-Response	Contains the response to the challenge of a dial-in client. Sent in an Access-Accept packet with Framed-Protocol of ARAP.
ARAP-Features	Includes password information that the network access server (NAS) must send to the user in an ARAP feature flags packet. Sent in an Access-Accept packet with Framed- Protocol of ARAP.
ARAP-Password	Appears in an Access-Request packet containing a Framed-Protocol of ARAP. Only one of User-Password, CHAP-Password, or ARAP-Password must be included in an Access-Request, or one or more EAP-Messages.
ARAP-Security	Identifies the ARAP security module to be used in an Access-Challenge packet.
ARAP-Security-Data	Contains the actual security module challenge or response, and is in Access-Challenge and Access-Request packets.
ARAP-Zone-Access	Indicates how to use the ARAP zone list for the user.
Access-Accept	Provides specific configuration information necessary to begin delivery of service to the user.
Access-Challenge	Sends the user a challenge requiring a response, and the RADIUS server must respond to the Access-Request by transmitting a packet with the Code field set to 11 (Access-Challenge).
Access-Reject	Transmits a packet with the Code field set to 3 (Access-Reject) if any value of the received Attributes is not acceptable.
Access-Request	Conveys information specifying user access to a specific NAS, and any special services requested for that user.
Accounting-Request	Conveys information used to provide accounting for a service provided to a user.
Accounting-Response	Acknowledges that the Accounting-Request has been received and recorded successfully.

Attribute	Description
Acct-Authentic	Indicates how the user was authenticated, whether by RADIUS, the NAS itself, or another remote authentication protocol.
Acct-Delay-Time	Indicates how many seconds the client has been trying to send this record.
Acct-Input-Gigawords	Indicates how many times the Acct-Input-Octets counter has wrapped around 2^{32} over the course of this service being provided.
Acct-Input-Octets	Indicates how many octets have been received from the port during the current session.
Acct-Input-Packets	Indicates how many packets have been received from the port during the session provided to a Framed User.
Acct-Interim-Interval	Indicates the number of seconds between each interim update in seconds for this specific session.
Acct-Link-Count	Indicates the count of links known to have been in each multilink session at the time the accounting record is generated.
Acct-Multi-Session-Id	Indicates a unique Accounting ID to make it easy to link together multiple related sessions in a log file.
Acct-Output-Gigawords	Indicates how many times the Acct-Output-Octets counter has wrapped around 2^{32} during the current session.
Acct-Output-Octets	Indicates how many octets have been sent to the port during this session.
Acct-Output-Packets	Indicates how many packets have been sent to the port during this session to a Framed User.
Acct-Session-Id	Indicates a unique Accounting ID to make it easy to match start and stop records in a log file.
Acct-Session-Time	Indicates how many seconds the user has received service.
Acct-Status-Type	Indicates whether this Accounting-Request marks the beginning of the user service (Start) or the end (Stop).

Attribute	Description
Acct-Terminate-Cause	Indicates how the session was terminated.
Acct-Tunnel-Connection	Indicates the identifier assigned to the tunnel session.
Acct-Tunnel-Packets-Lost	Indicates the number of packets lost on a given link.
CHAP-Challenge	Contains the Challenge Handshake Authentication Protocol (CHAP) challenge sent by the NAS to a PPP CHAP user.
CHAP-Password	Indicates the response value provided by a PPP CHAP user in response to the challenge.
Callback-Id	Indicates the name of a location to be called, to be interpreted by the NAS.
Callback-Number	The dialing string to be used for callback.
Called-Station-Id	Allows the NAS to send the phone number that the user called, using Dialed Number Identification Service (DNIS) or similar technology.
Calling-Station-Id	Allows the NAS to send the phone number that the call came from, using Automatic Number Identification (ANI) or similar technology.
Class	Sent by the server to the client in an Access-Accept and then sent unmodified by the client to the accounting server as part of the Accounting-Request packet, if accounting is supported.
Configuration-Token	Used in large distributed authentication networks based on proxy.
Connect-Info	Sent from the NAS to indicate the nature of the user's connection.
EAP-Message	Encapsulates Extended Access Protocol [3] packets to allow the NAS to authenticate dial-in users by means of EAP without having to understand the EAP protocol.
Event-Timestamp	Records the time that this event occurred on the NAS, in seconds since January 1, 1970 00:00 UTC.

Attribute	Description
Egress -VLAN-ID	The Egress-VLANID attribute represents an allowed Egress VLANID for this port, indicating if the VLANID is allowed for tagged or untagged frames as well as the VLANID.
Egress-VLAN-Name	The Egress-VLAN-Name attribute represents an allowed VLAN for this port. It is similar to the Egress-VLANID attribute, except that the VLAN-ID itself is not specified or known; rather, the VLAN name is used to identify the VLAN within the system.
Filter-Id	Indicates the name of the filter list for this user.
Framed-AppleTalk-Link	Indicates the AppleTalk network number used for the serial link to the user, which is another AppleTalk router.
Framed-AppleTalk-Network	Indicates the AppleTalk Network number which the NAS can probe to allocate an AppleTalk node for the user.
Framed-AppleTalk-Zone	Indicates the AppleTalk Default Zone to be used for this user.
Framed-Compression	Indicates the compression protocol to be used for the link.
Framed-IP-Address	Indicates the address to be configured for the user.
Framed-IP-Netmask	Indicates the IP netmask to be configured for the user when the user is a router to a network.
Framed-IPv6-Pool	Contains the name of an assigned pool used to assign an IPv6 prefix for the user.
Framed-IPv6-Prefix	Indicates an IPv6 prefix (and corresponding route) to be configured for the user.
Framed-IPv6-Route	Indicates the routing information to be configured for the user on the NAS.
Framed-IPv6 Address	Indicates an IPv6 address assigned to NAS interface of the host.

Attribute	Description
Framed-Interface-Id	Indicates the IPv6 interface identifier to be configured for the user.
Framed-IPX-Network	Indicates the IPX Network number to be configured for the user.
Framed-MTU	Indicates the maximum transmission unit to be configured for the user, when it is not negotiated by some other means (such as PPP).
Framed-Pool	Indicates the name of an assigned address pool used to assign an address for the user.
Framed-Protocol	Indicates the framing to be used for framed access.
Framed-Route	Indicates the routing information to be configured for the user on the NAS.
Framed-Routing	Indicates the routing method for the user, when the user is a router to a network.
Idle-Timeout	Sets the maximum number of consecutive seconds of idle connection allowed to the user before termination of the session or prompt.
Ingress-Filters	The Ingress-Filters attribute corresponds to the Ingress Filter per-port variable. Supports the following values: Disabled=2 Enabled= 1 When the attribute has the value "Enabled", the set of VLANs that are allowed to ingress a port must match the set of VLANs that are allowed to egress a port.
Keep-Alives	Uses SNMP instead of keepalives.
Login-IP-Host	Indicates the system with which to connect the user when the Login-Service Attribute is included.
Login-IPv6-Host	Indicates the system with which to connect the user when the Login-Service Attribute is included.
Login-LAT-Group	Contains a string identifying the LAT group codes that this user is authorized to use.

Attribute	Description
Login-LAT-Node	Indicates the node with which the user is to be automatically connected by LAT.
Login-LAT-Port	Indicates the port with which the user is to be connected by LAT.
Login-LAT-Service	Indicates the system with which the user is to be connected by LAT.
Login-Service	Indicates the service to use to connect the user to the log in host.
Login-TCP-Port	Indicates the TCP port with which the user is to be connected when the Login-Service Attribute is also present.
MS-ARAP-Challenge	Only present in an Access-Request packet containing a Framed-Protocol Attribute with the value 3 (ARAP).
MS-ARAP-Password-Change-Reason	Indicates the reason for a server-initiated password change.
MS-Acct-Auth-Type	Represents the method used to authenticate the dial-up user.
MS-Acct-EAP-Type	Represents the Extensible Authentication Protocol (EAP) type used to authenticate the dial-up user.
MS-BAP-Usage	Describes whether the use of BAP is allowed, disallowed, or required on new multilink calls.
MS-CHAP-CPW-1	Allows the user to change password if it has expired.
MS-CHAP-CPW-2	Allows the user to change password if it has expired.
MS-CHAP-Challenge	Contains the challenge sent by a NAS to a MS-CHAP user.
MS-CHAP-Domain	Indicates the Windows NT domain in which the user was authenticated.
MS-CHAP-Error	Contains error data related to the preceding MS-CHAP exchange.

Attribute	Description
MS-CHAP-LM-Enc-PW	Contains the new Windows NT password encrypted with the old LAN Manager password hash.
MS-CHAP-MPPE-Keys	Contains two session keys for use by the Microsoft Point-to-Point Encryption (MPPE).
MS-CHAP-NT-Enc-PW	Contains the new Windows NT password encrypted with the old Windows NT password hash.
MS-CHAP-Response	Contains the response value provided by a PPP MS-CHAP user in response to the challenge.
MS-CHAP2-CPW	Allows the user to change password if it has expired.
MS-CHAP2-Response	Contains the response value provided by an MS-CHAP-V2 peer in response to the challenge.
MS-CHAP2-Success	Contains a 42-octet authenticator response string.
MS-Filter	Transmits traffic filters.
MS-Link-Drop-Time-Limit	Indicates the length of time (in seconds) that a link must be underutilized before it is dropped.
MS-Link-Utilization-Threshold	Represents the percentage of available bandwidth utilization below which the link must fall before the link is eligible for termination.
MS-MPPE-Encryption-Policy	Signifies whether the use of encryption is allowed or required.
MS-MPPE-Encryption-Types	Signifies the types of encryption available for use with MPPE.
MS-MPPE-Recv-Key	Contains a session key for use by the MPPE.
MS-MPPE-Send-Key	Contains a session key for use by the MPPE.

Attribute	Description
MS-New-ARAP-Password	Transmits the new ARAP password during an ARAP password change operation.
MS-Old-ARAP-Password	Transmits the old ARAP password during an ARAP password change operation.
MS-Primary-DNS-Server	Indicates the address of the primary domain name server (DNS) server to be used by the PPP peer.
MS-Primary-NBNS-Server	Indicates the address of the primary NetBIOS name server (NBNS) server to be used by the PPP peer.
MS-RAS-Vendor	Indicates the manufacturer of the RADIUS client machine.
MS-RAS-Version	Indicates the version of the RADIUS client software.
MS-Secondary-DNS-Server	Indicates the address of the secondary DNS server to be used by the PPP peer.
MS-Secondary-NBNS-Server	Indicates the address of the secondary DNS server to be used by the PPP peer.
Message-Authenticator	Signs Access-Requests to prevent spoofing Access-Requests using CHAP, ARAP, or EAP authentication methods.
NAS-IP-Address	Indicates the identifying IP address of the NAS that is requesting authentication of the user, and must be unique to the NAS within the scope of the RADIUS server.
NAS-IPv6-Address	Indicates the identifying IPv6 Address of the NAS that is requesting authentication of the user, and must be unique to the NAS within the scope of the RADIUS server.
NAS-Identifier	Contains a string identifying the NAS originating the Access-Request.
NAS-Port	Indicates the physical port number of the NAS that is authenticating the user.
NAS-Port-Id	Contains a text string that identifies the port of the NAS that is authenticating the user.
NAS-Port-Type	Indicates the type of the physical port of the NAS that is authenticating the user.

Attribute	Description
Password-Retry	Indicates how many authentication attempts a user is allowed to attempt before being disconnected.
Port-Limit	Sets the maximum number of ports to be provided to the user by the NAS.
Prompt	Indicates to the NAS whether it should echo the user's response as it is entered, or not echo it.
Proxy-State	Indicates that a proxy server can send this attribute to another server when forwarding an Access-Request. The attribute must be returned unmodified in the Access-Accept, Access-Reject or Access-Challenge.
Reply-Message	Indicates that the text that can be displayed to the user.
Service-Type	Indicates the type of service the user has requested, or the type of service to be provided.
Session-Timeout	Sets the maximum number of seconds of service to be provided to the user before termination of the session or prompt.
State	Indicates that the packet must have only zero or one State Attribute. Usage of the State Attribute is implementation dependent.
Telephone-number	Using the Calling-Station-Id and Called-Station-Id RADIUS attributes, authorization and subsequent tunnel attributes can be based on the phone number originating the call, or the number being called.
Termination-Action	Indicates the action the NAS should take when the specified service is completed.
Tunnel-Assignment-ID	Indicates to the tunnel initiator the particular tunnel to which a session is to be assigned.
Tunnel-Client-Auth-ID	Specifies the name used by the tunnel initiator during the authentication phase of tunnel establishment.
Tunnel-Client-Endpoint	Contains the address of the initiator end of the tunnel.
Tunnel-Link-Reject	Indicates the rejection of the establishment of a new link in an existing tunnel.

Attribute	Description
Tunnel-Link-Start	Marks the creation of a tunnel link.
Tunnel-Link-Stop	Marks the destruction of a tunnel link.
Tunnel-Medium-Type	Indicates the transport medium to use when creating a tunnel for those protocols (such as L2TP) that can operate over multiple transports.
Tunnel-Medium-Type	Indicates the transport medium to use when creating a tunnel for those protocols (such as L2TP) that can operate over multiple transports.
Tunnel-Password	Specifies a password used to access a remote server.
Tunnel-Preference	Indicates that if RADIUS server returns more than one set of tunneling attributes to the tunnel initiator, you should include this attribute in each set to indicate the relative preference assigned to each tunnel.
Tunnel-Private-Group-ID	Indicates the group ID for a particular tunneled session.
Tunnel-Reject	Marks the rejection of the establishment of a tunnel with another node.
Tunnel-Server-Auth-ID	Specifies the name used by the tunnel terminator during the authentication phase of tunnel establishment.
Tunnel-Server-Endpoint	Indicates the address of the server end of the tunnel.
Tunnel-Start	Marks the establishment of a tunnel with another node.
Tunnel-Stop	Marks the destruction of a tunnel to or from another node.
Tunnel-Type	Indicates the tunneling protocol(s) to be used (in the case of a tunnel initiator) or the tunneling protocol in use (in the case of a tunnel terminator).
User-Name	Indicates the name of the user to be authenticated.
User-Password	Indicates the password of the user to be authenticated, or the user's input following an Access-Challenge.

Understanding RADIUS Accounting

You can configure the device to send session start and stop messages to a RADIUS accounting server. The device sends a user-session start message after the user successfully signs in and the device maps to a role.

Whenever a user session is terminated, the device sends a user-session stop message to the accounting server. A user session is terminated whenever the user:

- Manually signs out
- Times out because of either inactivity or exceeding the maximum session length
- Is denied access because of Host Checker role-level restrictions
- Is manually forced out by an administrator as a result of dynamic policy evaluation

If users are signed into a device cluster, the RADIUS accounting messages might show the users signing in to one node and signing out of another.

Table describes the attributes that are common to start and stop messages.

Attribute	Description
User-Name (1)	Specifies the string that the device administrator specifies during RADIUS server configuration.
NAS-IP-Address (4)	Specifies the device's IP address.
NAS-Port (5)	The device sets this attribute to 0 if the user signed in using an internal port, or 1 if an external port is used.
Framed-IP-Address (8)	Specifies the user's source IP address.
NAS-Identifier (32)	Specifies the configured name for the device client under the RADIUS server configuration.
Acct-Status-Type (40)	The device sets this attribute to 1 for a start message, or 2 for a stop message in a user-session or a subsession.
Acct-Session-Id (44)	Specifies the unique accounting ID that matches start and stop messages corresponding to a user-session or to a subsession.

Attribute	Description
Acct-Multi-Session-Id (50)	Specifies the unique accounting ID that you can use to link together multiple related sessions. Each linked session must have a unique Acct-Session-Id and the same Acct-Multi-Session-Id.
Acct-Link-Count (51)	Specifies the count of links in a multilink session at the time the system generates the accounting record.

Attribute	Description
Acct-Authentic (45)	<p>The device sets this attribute to:</p> <ul style="list-style-type: none">• RADIUS—if the user is authenticated to a RADIUS server.• Local—if the user is authenticated to a local authentication server.• Remote—if the user is authenticated through any other RADIUS server.

Attribute	Description
Acct-Session-Time (46)	Specifies the duration of the user-session or the subsession.
Acct-Terminate-Cause (49)	<p>The device uses one of the following values to specify the event that caused the termination of a user session or a subsession:</p> <ul style="list-style-type: none">• User Request (1) – User manually signs out.• Idle Timeout (4) – User is Idle and times out.• Session Timeout (5) – User's maximum session times out.• Admin Reset (6) – User is forced out from active user's page.

Interoperability Requirements and Limitations

You must configure the third-party RADIUS server to communicate with the access management framework.

On the RADIUS server, configure the following settings:

- Hostname.
- Network IP address.
- Client type, if applicable. If this option is available, select Single Transaction Server or its equivalent.
- Type of encryption for authenticating client communication. This choice should correspond to the client type.
- Shared secret.

The following are the requirements and limitations for Interim update feature:

- If you want a server to receive interim accounting messages, you can statically configure an interim value on the client, in which case, the locally configured value overrides any value that might be included in the RADIUS Access-Accept message.
- The octet count reported in the accounting messages is the cumulative total since the beginning of the user session.
- The interim update byte count is only supported based on a user session, not on SAM or NC sessions.

Configuring Authentication with a RADIUS Server

To configure authentication with the RADIUS server:

1. Select **Authentication > Auth. Servers**.
2. Select **RADIUS Server** and click **New Server** to display the configuration page.
3. Complete the configuration as described below.
4. Save the configuration.

Auth Servers > IPv6-SBR-SRV

IPv6-SBR-SRV

Settings Users

*Name: Label to reference this server.

NAS-Identifier: Name of the device as known to RADIUS server

Primary Server

*RADIUS Server: Name or IP address

*Authentication Port:

*Shared Secret:

*Accounting Port: Port used for RADIUS accounting, if applicable

NAS-IP-Address: IP address

*Timeout: seconds

*Retries:

☐ Users authenticate using tokens or one-time passwords

Backup Server (required only if Backup server exists)

RADIUS Server: Name or IP address

Authentication Port:

Shared Secret:

Accounting Port: Port used for RADIUS accounting, if applicable

☐ Load-Balance Auth Requests between Primary and Backup Servers
Accounting requests will not be load-balanced.

RADIUS accounting

User-Name: Template for reporting user identity to RADIUS server
The template can contain textual characters as well as variables for substitution. Variables should be enclosed in angle brackets like this <variable>. Click [here](#) to view a list of all variables.

Examples:
 <USER> The user's login name
 <REALM> The user's sign-in realm
 <ROLE SEP>";" The list of ";"-separated roles assigned to the user
 <ROLE> The first role amongst multiple roles assigned to the user

Interim Update Interval: minutes Time interval to send an interim update to the accounting server (min: 15 minutes, max: 1440 minutes)

Settings	Guidelines
Name	Specify a name to identify the server within the system.
NAS-Identifier	<p>Specify the name that identifies the Network Access Server (NAS) client to the RADIUS server.</p> <hr/> <div>  <ul style="list-style-type: none"> - If you do not specify the NAS identifier, the value specified in the Hostname field on the System > Network > Overview page of the administrator console is used. - If you use the RADIUS proxy feature, the NAS-Identifier field is not used. Proxy passes on the entire RADIUS packet including the NAS identifier from the client. </div> <hr/>

Settings	Guidelines
Primary Server	
Radius Server	Specify the name or IPv4/IPv6 address of the RADIUS server.
Authentication Port	Specify the authentication port value for the RADIUS server. Default port number: 1812, 1645 (legacy servers)
NAS-IP-Address	<p>Specify the NAS IP address.</p> <hr/> <ul style="list-style-type: none"> - If you leave this field empty, the internal IP address is passed to RADIUS requests. - If you configure the NAS IP address, then the system passes the value regardless of which cluster node sends the requests. - If you use the RADIUS proxy feature, this field is not used. - Proxy passes on the entire RADIUS packet including the NAS IP address from the client. <hr/>
Timeout (seconds)	Specify the interval of time to wait for a response from the RADIUS server before timing out the connection.
Retries	Specify the number of times to try to make a connection after the first attempt fails.
Users authenticate using tokens or one-time passwords.	<p>Select this option to prompt the user for a token instead of a password. For example, you can use this option to dynamically prompt for a password or token based on sign-in policies by configuring two instances of the same authentication server. You can use one instance for wireless users with this option enabled and that prompts the user for a token, and another instance for wired users with this option disabled and that prompts the user for a password.</p> <hr/> <p> If you are using RADIUS proxy feature, this option is not used.</p> <hr/>
Backup Server (required only if Backup server exists)	
Radius Server	<p>Specify the secondary RADIUS server.</p> <p>The authentication request is first routed to the primary RADIUS server, then to the specified backup server if the primary server is unreachable.</p> <p>Accounting messages are sent to the RADIUS server by each cluster node without consolidation.</p> <p>RADIUS accounting follows these assumptions:</p>

Settings	Guidelines
	<ul style="list-style-type: none"> If the cluster is active/passive, all users are connected to one node at a time. If the cluster is active/active and does not use a balancer, users are connected to different nodes but are static. If the cluster is active/active and uses a balancer, the balancer usually enforces a persistent source IP. In this case, users are always connected to the same node. <hr/> <p> RADIUS does not support load balancing.</p>
Authentication Port	Specify the authentication port.
Shared Secret	Specify the shared secret.
Accounting Port	Specify the accounting port.
Radius Accounting	
User-Name	<p>Specify the user information to the RADIUS accounting server. You can enter any of the applicable session variables. Applicable variables include those that are set the time after the user signs in and maps to a role. The default variables for this field are as follows:</p> <ul style="list-style-type: none"> USER: Logs the username to the accounting server. REALM: Logs the realm to the accounting server. ROLE SEP="," : Logs the list of comma-separated roles assigned to the user. ROLE: Logs the role to the accounting server. <hr/> <p> If you assign the user to more than one role, the system separates them with commas.</p>
Interim Update Interval (minutes)	Select this option to achieve more precise billing for long-lived session clients and during network failure.

Settings	Guidelines
	<ul style="list-style-type: none"> - If you are using the RADIUS proxy feature, the fields in this section are not used. - The minimum interim update interval is 15 minutes. The data statistics (bytes in and bytes out) for RADIUS accounting might not be sent for a J-SAM/W-SAM/NC session if the session is less than 30 seconds long and the applications keep the connections open all the time.
Custom challenge expressions	
<p>(Optional) Three types of challenge expressions exist with each automatically set to its pre-populated default. The custom option allows the administrator to configure the actual string pattern to match for any of the three modes. To add a custom expression, select the check box for the appropriate challenge expression type, and add a custom expression in the associated text box.</p> <ul style="list-style-type: none"> - If you use SecureID to authenticate users, then provide the user ID and the concatenation of PIN and the token value. - When using CASQUE authentication, specify:([0-9a-zA-Z/+=]+): as the custom expression for the Generic Login Challenge Expression. - If you are using the RADIUS proxy feature, the fields in this section are not used. 	
Next Token	Specify the appropriate Next Token.
New PIN	Specify the New PIN.
Generic Login	Specify the Generic Login challenge to the user.

Using an ACE Server

This topic describes integration with an ACE Server (now named RSA Authentication Manager).

RSA Authentication Manager Overview

This section describes support for using IPS with an ACE Server (now named RSA Authentication Manager).

Understanding RSA Authentication Manager

[RSA Authentication Manager](#) (formerly known as ACE/Server) is an authentication and authorization server that allows user authentication based on credentials from the RSA SecurID® product from RSA Security Inc.

When you use RSA Authentication Manager as the authentication and authorization service for your access management framework, users can sign in to IPS using the same username and password stored in the backend server.

Table describes RSA SecurID hardware token and software token user sign-in methods.

Method	Action
Using a hardware token and the standard system sign-in page	The user browses to the standard system sign-in page, and then enters the username and password (consisting of the concatenation of the PIN and the RSA SecurID hardware token's current value). The system then forwards the user's credentials to the authentication server.
Using a software token and the custom SoftID system sign-in page	The user browses to the SoftID custom sign-in page. Then, using the SoftID plug-in, the user enters the username and PIN. The SoftID plug-in generates a passphrase by concatenating the user's PIN and token and passes the passphrase to the authentication server.

If the RSA Authentication Manager positively authenticates the user, the user gains access to the system. Otherwise, the RSA Authentication Manager:

- Denies the user access to the system.
- Prompts the user to generate a new PIN (New PIN mode) if the user is signing in to the system for the first time. Users see different prompts depending on the method they use to sign in.
- If the user signs in using the SoftID plug-in, then the RSA prompts the user to create a new pin; otherwise IPS prompts the user to create a new PIN.
- Prompts the user to enter the next token (Next Token mode) if the token entered by the user is out of sync with the token expected by RSA Authentication Manager. Next Token mode is transparent to users signing in using a SoftID token. The RSA SecurID software passes the token through the system to RSA Authentication Manager without user interaction.

- Redirects the user to the standard system sign-in page (SoftID only) if the user tries to sign-in to the RSA SecurID Authentication page on a computer that does not have the SecurID software installed.

Feature Support

Access management framework supports the following RSA Authentication Manager features:

- New PIN mode
- Next-token mode
- Data Encryption Standard (DES)/ Secure Dial-In (SDI) encryption
- Advanced Encryption Standard (AES) encryption
- Slave Authentication Manager support
- Name locking
- Clustering

Interoperability Requirements and Limitations

The following limitations apply when defining and monitoring an RSA Authentication Manager instance:

- You can only add one RSA Authentication Manager configuration to the system, but you can use that configuration to authenticate any number of realms.
- You cannot customize the load balancing algorithm.
- When you enter the New PIN or Next Token mode, enter the required information within three minutes. Otherwise, the system cancels the transaction and notifies the user to reenter the credentials.
- The system can handle a maximum of 200 RSA Authentication Manager transactions at any given time. A transaction only lasts as long as is required to authenticate against the RSA Authentication Manager.

For example, when a user signs into the system, the RSA Authentication Manager transaction is initiated when the user submits the request for authentication and ends once the RSA Authentication Manager has finished processing the request. The user may then keep his or her session open, even though the RSA Authentication Manager transaction is closed.

Configuring Authentication with RSA Authentication Manager

To configure authentication with an ACE server:

1. Select **Authentication > Auth. Servers**.
2. Select **ACE Server** and click **New Server** to display the configuration page.
3. Complete the configuration as described in table.
4. Save the configuration.

Auth Servers > New ACE Server

New ACE Server

Settings	Guidelines
Name	Specify a name to identify the server within the system.
ACE Port	<div>Specify the default port of the authentication server.</div> <div><div>i</div><div>If no port is specified in the sdconf.rec file, the default port is used.</div></div>
Configuration File	

Settings	Guidelines
Current config file	Specify the RSA Authentication Manager configuration file.  You must update this file on the device anytime you make changes to the source file.
Imported on	Display the date on which the config file is imported.
Import new config file	Use the Choose File button to upload the sdconf.rec configuration file.
Node Verification File	
Node	Save the configuration to redisplay the configuration page. The updated page includes a section that lists a timestamp for the negotiation of the node secret between the system and the backend RSA server. The negotiation and verification automatically occurs after first successful log in. Do not expect entries in the table until at least one user has authenticated successfully.

Displaying the User Accounts Table

1. To display user accounts:
2. Select **Authentication > Auth. Servers**.
3. Click the link for the authentication server you want to manage.
4. Click the **Users** tab to display the user accounts table.

The user accounts table includes entries for the accounts that have been created. The Last Sign-in Statistic column shows the last successful sign-in date and time for each user, the user's IP address, and the agent or browser type and version.

Use the controls to search for users and manage user accounts:

- To search for a specific user, enter a username in the Show users named box and click **Update**.

You can use an asterisk (*) as a wildcard, where * represents any number of zero or more characters. For example, to search for all usernames that contain the letters jo, enter *jo*. The search is case-sensitive. To display the entire list of accounts again, type * or delete the field's contents and click **Update**.

- To limit the number of users displayed on the page, enter a number in the Show N users box and click Update.
- To terminate the user session and delete the account, select the check box next to the user account record and click Delete.

Using the SAML Server

This topic describes the local SAML authentication server. It includes the following information:

Overview

This section describes support for using the local SAML authentication server. It includes the following sections:

Understanding SAML

SAML is an XML-based framework for communicating user authentication, entitlement, and attribute information. The standard defines the XML-based assertions, protocols, bindings, and profiles used in communication between SAML entities. SAML is used primarily to implement Web browser single sign-on (SSO). SAML enables businesses to leverage an identity-based security system like Connect Secure to enforce secure access to web sites and other resources without prompting the user with more than one authentication challenge.

For complete details on the SAML standard, see the OASIS web site:

http://www.oasis-open.org/committees/tc_home.php?wg_abbrev=security

SAML Feature Support

When deployed as SAML service provider, IPS runs a local SAML server that relies on the SAML identity provider authentication and attribute assertions when users attempt to sign in to IPS. Note that authentication is only part of the IPS security system. The access management framework determines access to the system and protected resources.

IPS supports:

- HTTP Redirect binding for sending AuthnRequests
- HTTP Redirect binding for sending/receiving SingleLogout requests/responses
- HTTP POST and HTTP Artifact bindings for receiving SAML responses
- RequestedAuthnContext context class specifications

IPS currently supports SAML server as Service Provider and IPS as SAML Identity Provider (IdP) is not supported.

Interoperability Requirements and Limitations

Before you begin:

- Check to see whether the SAML identity provider implements SAML 2.0 or SAML 1.1.
- Check to see whether the SAML identity provider uses HTTP POST or HTTP Artifact bindings for SAML assertions.
- Check to see whether the SAML identity provider has published a SAML metadata file that defines its configuration. If the SAML identity provider metadata file is available, configuration is simpler and less prone to error.
- Complete the system-wide SAML settings if you have not already done so. Select **System > Configuration > SAML > Settings**. For details, see [Configuring Global SAML Settings](#)
- Add metadata for the SAML identity provider to the metadata provider list if you have not already done so. Select **System > Configuration > SAML**. For details, see [Managing SAML Metadata Files](#).

The sign-in URL for which a session needs to be established for Connect Secure as a service provider is identified by the RelayState parameter (HTTP URL parameter for artifact and HTML form parameter for POST.) In a service provider initiated case, the system populates RelayState as an HTTP URL parameter while sending AuthnRequest. In the IdP-Initiated scenario (Connect Secure is a service provider and there is a third-party IdP), the IdP must be configured to set the appropriate Sign-in URL of Connect Secure in the RelayState parameter of the HTML form containing the SAML response. For more information, see [SAML Feature Support](#).

Configuring Authentication with the SAML Server

To configure the SAML server:

1. Select **Authentication > Auth. Servers**.
2. Select **SAML Server** and click **New Server** to display the configuration page.
3. Complete the configuration as described in table.
4. Save the configuration.

Settings	Guidelines
Name	Specify a name to identify the server instance.
Settings	
SAML Version	Select 2.0 or 1.1, depending on the SAML version used by the SAML IdP.
Policy Secure Entity Id	This value is prepopulated. It is generated by the system, based on the value for the Host FQDN for SAML setting on the System > Configuration > SAML > Settings page.
Configuration Mode	Select Manual or Metadata. If a metadata file or location is available from the SAML identity provider, use the metadata option to make configuration simpler and less prone to error. To upload or set the location for the published metadata file, select System > Configuration > SAML and click the New Metadata Provider button.
Identity Provider Entity ID	The identity provider entity ID is sent as the Issuer value in the assertion generated by the SAML identity provider.

Settings	Guidelines
	<p>If you use the metadata option, this setting can be completed by selecting the identity provider entity ID from the list. The list is populated by the identity provider entities defined in metadata files added to the System > Configuration > SAML page.</p> <p>If you complete this setting manually, specify the Issuer value in assertions generated by the SAML identity provider. Typically, you ask the SAML identity provider administrator for this setting.</p>
Identity Provider Single Sign On Service URL	<p>The identity provider SSO service URL is a URL provisioned by the SAML identity provider. The setting is required to support service-provider-initiated SSO. If missing, the system cannot successfully redirect the user request.</p> <p>If you use the metadata option, this setting can be completed by selecting the SSO service URL from the list. The list is populated by the identity provider entities defined in metadata files added to the System > Configuration > SAML page.</p> <p>If you complete this setting manually, ask the SAML identity provider administrator for this setting.</p>
User Name Template	<p>Specify how the system is to derive the username from the assertion. If the field is left blank, it uses the string received in the NameID field of the incoming assertion as the username.</p> <p>If you choose a certificate attribute with more than one value, the system uses the first matched value. For example, if you enter <certDN.OU> and the user has two values for the attribute (ou=management, ou=sales), the system uses "management". To use all values, add the SEP attribute to the variable. For example, if you enter <certDN.OUT SEP=":">, the system uses "management:sales". The attributes received in the attribute statement in the incoming assertion are saved under userAttr. These variables can also be used with angle brackets and plain text. If the username cannot be generated using the specified template, the login fails. If the NameID field of the incoming assertion is of type X509Nameformat, then the individual fields can be extracted using system variable "assertionNameDN".</p>

Settings	Guidelines
	<p> Currently supported NameIDs are - EMAIL, X509_SUBJECT, WIN_DOMAIN_QUALIFIED. If a SAML request is received with a different NameId format, then processing of the request fails with unsupported NameId format error message.</p>
Allowed Clock Skew (minutes)	<p>Specify the maximum allowed difference in time between the system clock and the SAML identity provider server clock.</p> <p> SAML is a time sensitive protocol. The time-based validity of a SAML assertion is determined by the SAML identity provider. If the SAML identity provider and SAML service provider clocks are askew, the assertion can be determined invalid, and you will receive the following error:</p> <p>"SAML Transferred failed. Please contact your system administrator. Detail: Failure: No valid assertion found in SAML response."</p> <p>Ensure that the clocks are synchronized using NTP server and that you set an Allowed Clock Skew value that accommodates any expected or permissible skew.</p>
Support Single Logout	<p>Single logout is a mechanism provided by SAML for logging out a particular user from all the sessions created by the identity provider. Select this option if the system must receive and send a single logout request for the peer SAML identity provider.</p> <p>If you use the metadata option, the Single Logout Service URL setting can be completed by selecting the SLO service URL from the list. The list is populated by the identity provider entities defined in metadata files added to the System > Configuration > SAML page. The system sends Single Logout requests to this URL.</p> <p>In addition, if you use the metadata option, the Single Logout Response URL setting is completed based on your selection for Single Logout Service URL. If the identity provider has left this setting empty in its metadata file, the system sends the Single Logout response to the SLO service URL.</p> <p>If you complete these settings manually, ask the SAML identity provider administrator for guidance.</p> <p>The Support Single Logout service for the identity provider must present a valid certificate.</p>

Settings	Guidelines
	This feature is supported with Ivanti Secure Access Client.
SSO Method	
Artifact	<p>When configured to use the Artifact binding, the system contacts the Artifact Resolution Service (ARS) to fetch the assertion using SOAP protocol. If the ARS is hosted on a HTTPS URL, then the certificate presented by the ARS is verified by the system. For this verification to pass successfully, the CA of the server certificate issued to the identity provider ARS must be added to the trusted server CA on the system.</p> <p>Complete the following settings to configure SAML using the HTTP Artifact binding:</p> <ul style="list-style-type: none">• Source ID. Enter the source ID for the identity provider ARS. Source ID is Base64-encoded, 20-byte identifier for the identity provider ARS. If left blank, this value is generated by the system.• Source Artifact Resolution Service URL. For metadata-based configuration, this field is completed automatically from the metadata file and is not configurable. For manual configurations, enter the URL of the service to which the SP ACS is to send ArtifactResolve requests. ArtifactResolve requests are used to fetch the assertion from the artifact received by it.• SOAP Client Authentication. Select HTTP Basic or SSL Client Certificate and complete the related settings. If you use an SSL client certificate, select a certificate from the device certificate list.• Select Device Certificate for Signing. Select the device certificate the system uses to sign the AuthnRequest sent to the identity provider SSO service. If you do not select a certificate, the system does not sign AuthnRequest.• Select Device Certificate for Encryption. Select the device certificate the system uses to decrypt encrypted data received in the SAML response. The public key associated with the device certificate is used by the identity provider for encryption.

Settings	Guidelines
POST	<p>When configured to use the POST binding, the system uses a response signing certificate to verify the signature in the incoming response or assertion. The certificate file must be in PEM or DER format. The certificate you select should be the same certificate used by the identity provider to sign SAML responses. Complete the following settings to configure SAML using the HTTP POST binding:</p> <ul style="list-style-type: none"> • Response Signing Certificate. If you use the metadata-based configuration option, select a certificate from the list. The list is populated by the identity provider entities defined in metadata files added to the System > Configuration > SAML page. <p>If you configure these settings manually, browse to and upload the certificate to be used to validate the signature in the incoming response or assertion. If no certificate is specified, the certificate embedded in the response is used.</p> <ul style="list-style-type: none"> • Enable Signing Certificate status checking. Select this option to check the validity of the signing certificate before verifying the signature. This setting applies to any certificate used for signature verification. If this option is enabled, the response will be rejected if the certificate is revoked, expired, or untrusted. If this option is selected, the certificate CA must be added to the Trusted Client CA store. <p>If this option is not enabled, then the certificate is used without any checks.</p> <ul style="list-style-type: none"> • Select Device Certificate for Signing. Select the device certificate the system uses to sign the AuthnRequest sent to the identity provider SSO service. If you do not select a certificate, the system does not sign AuthnRequest. • Select Device Certificate for Encryption. Select the device certificate the system uses to decrypt encrypted data received in the SAML response. The public key associated with the device certificate is used by the identity provider for encryption.
Authentication Context Classes	<p>Use the Add and Remove buttons to select authentication context classes to be sent in the authentication requests to the SAML identity provider. These are included in the RequestedAuthnContext element.</p>

Settings	Guidelines
	<p>In the OASIS standard, an authentication context is defined as “the information, additional to the authentication assertion itself, that the relying party may require before it makes an entitlements decision with respect to an authentication assertion.”</p> <p>This feature supports all authentication context classes specified in the SAML 2.0 OASIS Authn Context specification</p> <p>For example, if you select X509, the system sends the following context:</p> <pre><samlp:RequestedAuthnContext> <saml:AuthnContextClassRef xmlns:saml="urn:oasis:names:tc:SAML:2.0:assertion"> urn:oasis:names:tc:SAML:2.0:ac:classes:X509</saml:AuthnContextClassRef> </samlp:RequestedAuthnContext></pre> <p>In response, the SAML IdP sends the context data along with the authentication results. The system stores the context data in the session cache and as a system variable named samlAuthnContextClass. The system variable can be used in role mapping rules and resource policy detailed rules.</p> <p>Specify a comparison attribute within the RequestedAuthnContext element. The comparison attribute specifies the relative strengths of the authentication context classes specified in the request and the authentication methods offered by a SAML IdP. The following values defined in the SAML 2.0 OASIS core specification can be selected:</p> <ul style="list-style-type: none">• exact—Requires the resulting authentication context in the authentication statement to be the exact match of at least one of the authentication contexts specified.• minimum—Requires the resulting authentication context in the authentication statement to be at least as strong as one of the authentication contexts specified.• maximum—Requires the resulting authentication context in the authentication statement to be stronger than any one of the authentication contexts specified.

Settings	Guidelines
	<ul style="list-style-type: none">• better—Requires the resulting authentication context in the authentication statement to be as strong as possible without exceeding the strength of at least one of the authentication contexts specified. <p>Select the same value that is configured on the SAML IdP. If none is specified in the SAML IdP configuration, the implicit default is exact.</p>
Service Provider Metadata Settings	
Metadata Validity	Enter the number of days the metadata is valid. Valid values are 0 to 9999. 0 specifies the metadata does not expire.
Do Not Publish IPS Metadata	Select this option if you do not want to publish the metadata at the location specified by the Entity ID field.
Download Metadata	This button appears only after you have saved the authentication server configuration. Use this button to download the metadata of the current SAML service provider.

Displaying the User Accounts Table

To display user accounts, refer to the steps found in [Displaying the User Accounts Table](#).

Access Control with SAML Server

In a SAML deployment, a SAML service provider is configured to request authentication from a SAML identity provider. The SAML identity provider responds with assertions regarding the identity, attributes, and entitlements (according to your configuration). The exchange enforces security and enables the SSO user experience.

IPS as a SAML Service Provider

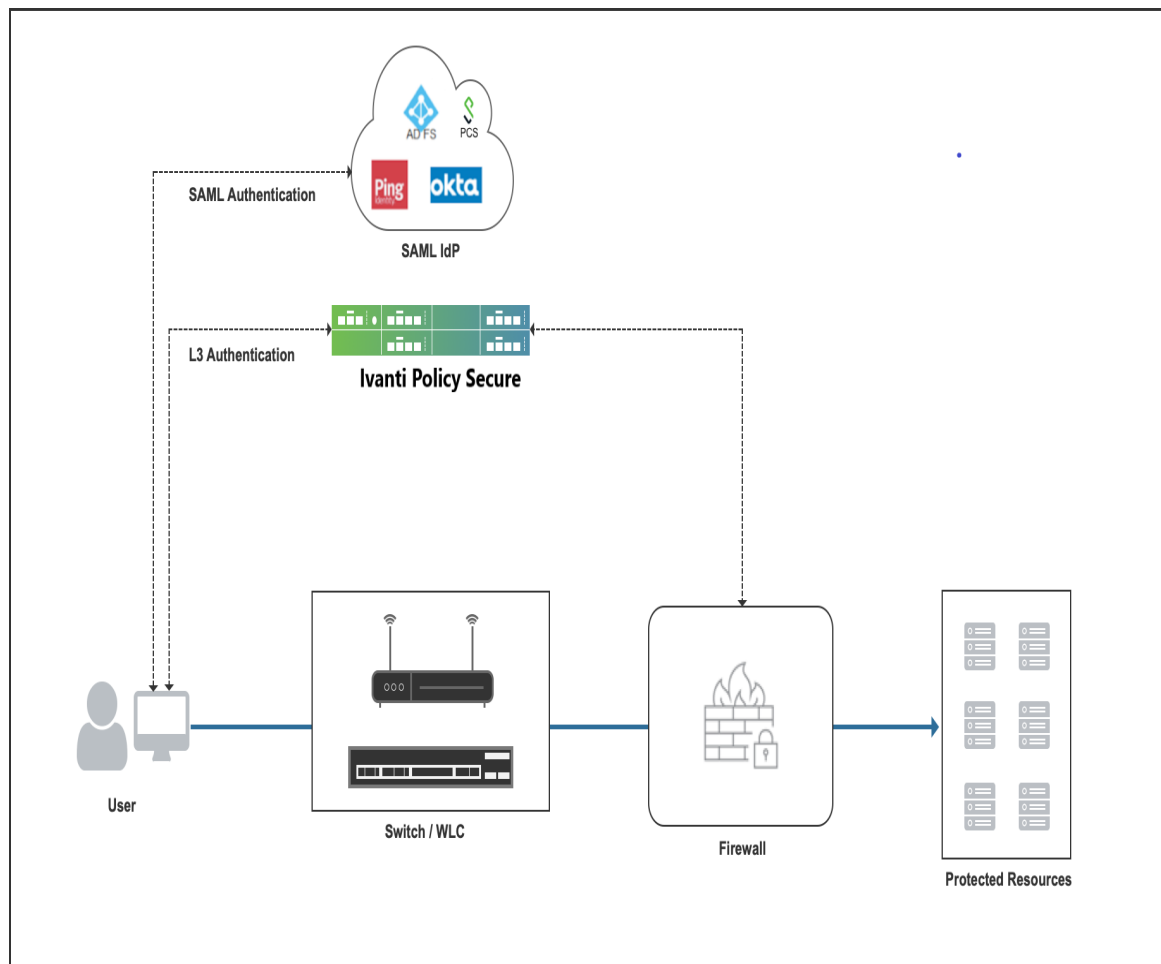

If you are working with a partner that has implemented a SAML identity provider, you can deploy the IPS as a SAML service provider to inter-operate with it, thereby enabling SSO for users who should have access to protected resources. In this model, the user is authenticated by the SAML identity provider. The system uses the SAML response containing the assertion to make an authentication decision.

The choices the identity provider makes to implement SAML determine the deployment choices, for example whether to use SAML 2.0 or SAML 1.1, whether to reference a published metadata configuration file, and whether to use a POST or artifact profile. When you deploy the system as a SAML service provider, you create a SAML authentication server configuration that references the partner SAML identity provider, and a set of access management framework objects (realm, role mapping rules, and sign-in policy) that reference the SAML authentication server.

Layer 3 Authentication and Enforcement using SAML Server

Figure shows how to access firewall protected resources using SAML server on IPS.

1. End user using an user agent (either a browser or a Ivanti Secure Access Client) authenticates to IPS

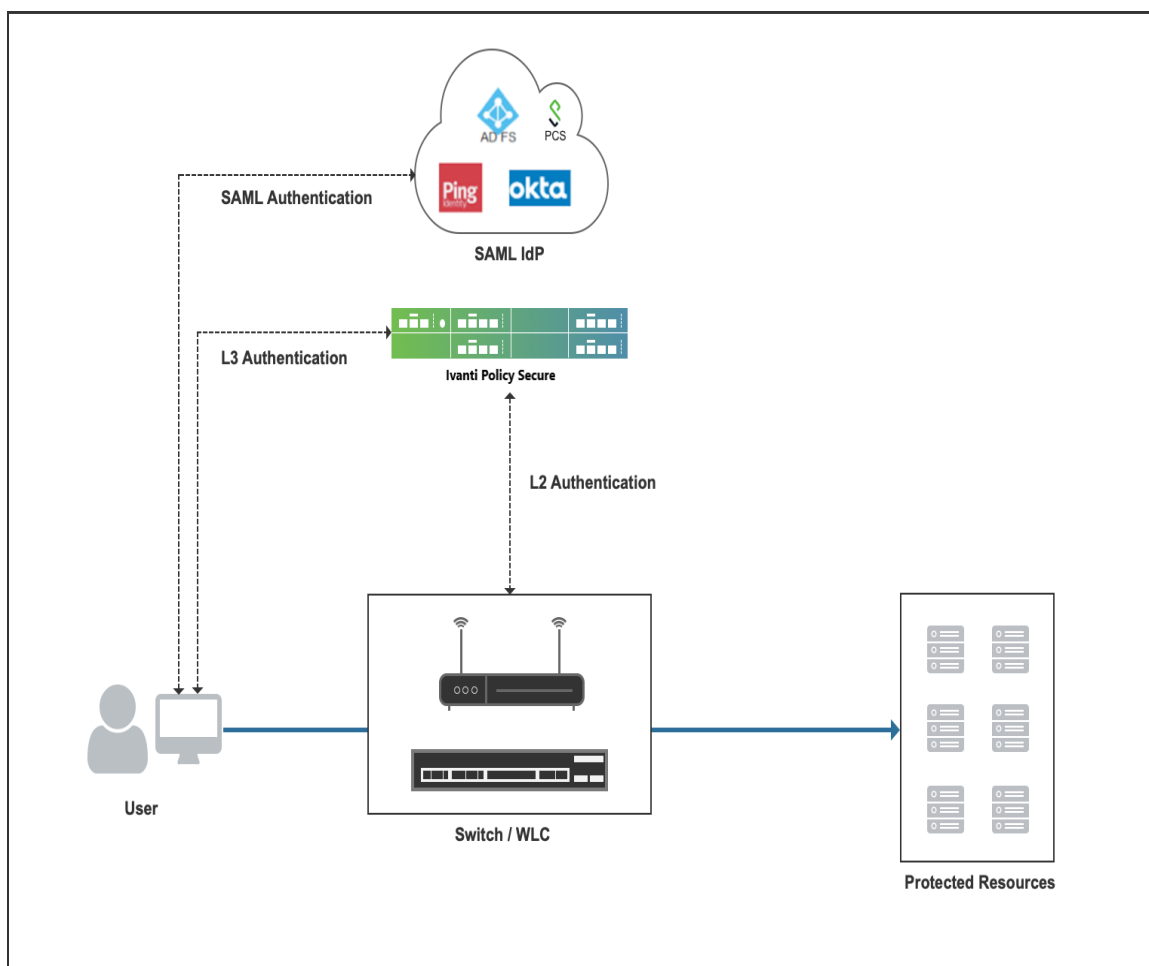

2. Ivanti Policy Secure(IPS) acting as a SAML Service Provider (SP), issues a SAML authentication (SAML AuthN) request to SAML IdP through the user agent. If SAML authentication request is valid, IdP authenticates the end user and generates SAML assertion and sends it to IPS (SAML SP) through user agent.
3. Ivanti Policy Secure(IPS) validates the SAML assertion and if it's valid, authentication is successful.
4. The user is first authenticated with SAML IdP. Once end user is authenticated appropriate role is assigned and the user ID is pushed to firewall. The end user can access the protected resource.

Ivanti Secure Access Client uses embedded browser for SAML authentication. It should be enabled on the Ivanti Secure Access Client connection settings in IPS.

Layer 2 Authentication and Enforcement using SAML Server

Figure shows how to access switch protected resources using SAML server on IPS.

For Layer 2 access control using SAML server on IPS, below mechanism is used:

1. MAC address authentication is performed using either RADIUS or SNMP for Layer 2 authentication. The session is created on IPS after successful MAC authentication and the user is provided with a limited access role since the Host Checker is not performed.
2. The user must be able to access both IPS and SAML IdP after L2 authentication. For policy enforcement using MAC address authentication, see here.
3. Ivanti Secure Access Client or web browser is used to perform Layer 3 authentication using SAML server.
4. After successful Layer 3 authentication on IPS via SAML IdP, both Layer 2 (MAC authentication) and Layer 3 (SAML authentication) connections are bridged using MAC address.

5. Host Checker is performed and if the SAML authentication is successful the user is provided with Full Access Role.
6. The user can access protected resources.

Layer 2 session is updated with the RADIUS attributes of the Layer 3 connection. The bridged session is used to perform Layer 2 access control. For more information on session bridging, see [here](#).

SAML 2.0 Configuration Tasks

To use SAML server on IPS follow the below configuration steps:

Configure SAML host FQDN under Configuration > SAML > Settings. This FQDN is used to generate SAML Entity Id. See [Configuring System-Wide SAML Settings](#)

Configure third party

SAML IdP like Ping Federate, Okta. Get SAML IdP metadata and configure it under Configuration > SAML > New Metadata Provider. Under Metadata Provider configuration, "Identity Provider" roles should be selected since it is an SAML IdP metadata. (For screenshot, refer section "Admin UI changes")

Configure SAML Server under

1. Authentication > Auth. Server. See [Configuring SAML Authentication server](#).
 - If SAML IdP's metadata is not configured, admin needs to configure IdP's information manually.
 - If only one IdP metadata is configured, IdP information is automatically populated. If multiple IdP metadata are configured, admin needs to select appropriate IdP's information.
 - If admin wants to sign or encrypt the request, appropriate certificates need to be selected.

After configuring SAML server on IPS, the metadata of IPS acting as an SAML SP can be downloaded from SAML server page.

Configure IPS metadata on SAML IdP and configured SAML SP details on IdP. See [Configuring IPS as a SAML 2.0 Service Provider](#)

Configuring System-Wide SAML Settings

This section describes tasks related to configuring system-wide SAML settings. It includes the following topics:

Configuring Global SAML Settings

The system-wide SAML settings impact all SAML service provider and identity provider instances.

To configure global SAML settings:

1. Select **System > Configuration > SAML**.
2. Click the **Settings** button to display the configuration page.
3. Complete the settings described in
4. Click Save Changes.

The screenshot shows the 'SAML > Settings' configuration page. It features a section titled '▼ Metadata Server Configuration' with three settings:

- Timeout value for metadata fetch request:** A text input field containing '300' followed by the unit 'seconds'. A tooltip indicates the range is '1 - 600. Specifies the time in seconds to wait for response of SAML metadata fetch request.'
- Validity of uploaded/downloaded metadata file:** A text input field containing '0' followed by the unit 'days'. A tooltip indicates the range is '0 - 9999. Specifies the time in days after which downloaded/uploaded metadata file expires. 0 means that Policy Secure doesnot enforce any validity on the peer metadata file.'
- Host FQDN for SAML:** An empty text input field. A tooltip indicates it is 'The FQDN used for generating URLs for SAML services.'

At the bottom of the form are three buttons: 'Save Changes', 'Cancel', and 'Update Entity Ids'.

Settings	Guidelines
Timeout value for metadata fetch request	Specify the number of seconds after which a download request is abandoned. If the peer SAML entity publishes its metadata at a remote location, the system downloads the metadata file from the specified location.
Validity of uploaded/downloaded metadata file	Specify the maximum duration for which the system considers the metadata file of the peer SAML entity to be valid. If the metadata file provided by the peer SAML entity contains validity information, the lower value takes precedence.
Host FQDN for SAML	<p>Specify the fully qualified domain name for the Connect Secure host. The value you specify here is used in the SAML entity ID and the URLs for SAML services, including:</p> <ul style="list-style-type: none">• Entity ID for SAML service provider and SAML identity provider instances. The SAML entity ID is the URL where the system publishes its SAML metadata file.• Single sign-on service URL• Single logout service URL• Assertion consumer service URL• Artifact resolution service URL <p>BEST PRACTICE: The system uses HTTPS for these services. It is recommend to assign a valid certificate to the interface that has the IP address to which this FQDN resolves so that users do not see invalid certificate warnings.</p>

Managing SAML Metadata Files

You use the System > Configuration > SAML pages to maintain a table of SAML metadata files for the SAML service providers and identity providers in your network. Using SAML metadata files makes configuration easier and less prone to error.

You can add the metadata files to the system by:

- Uploading a metadata file.
- Retrieving the metadata file from a well-known URL.

To add metadata files:

1. Select **System > Configuration > SAML**.
2. Click **New Metadata Provider** to display the configuration page.
3. Complete the settings described in table.
4. Save the configuration.

SAML > New Metadata Provider

Name: Label to reference metadata provider.

▼ Metadata Provider Location Configuration

Location: ☒ Local ☐ Remote Location of metadata provider. In case of Local, metadata file needs to be uploaded by admin. In case of Remote Location, metadata file is fetched by Policy Secure from the configured download url.

Upload Metadata File: No file chosen
Current File: None

▼ Metadata Provider Verification Configuration

☐ Accept Unsigned Metadata If checked Policy Secure accepts unsigned metadata.

Signing Certificate:
Issued To:
Issued By:
Valid:
Details: [Other Certificate Details](#)

Upload Certificate: No file chosen
☐ Enable Signing Certificate status checking
(Uses configuration in Trusted Client CAs. This applies to the certificate configured above as well as the one comes along with the Metadata.)

▼ Metadata Provider Filter Configuration

Roles: ☒ Identity Provider ☐ Service Provider ☐ Policy Decision Point Roles which Policy Secure looks for in the metadata file.

Entity Ids to import: List of entity ids to be imported. (one per line). If left empty all entity ids in the file are imported.

Settings	Guidelines
Metadata Provider Location Configuration	<p>Select one of the following methods:</p> <ul style="list-style-type: none"> Local. Browse and locate the metadata file on your local host or file system. Remote. Enter the URL of the metadata file. Only http and https protocols are supported.
Metadata Provider Verification Configuration	
Accept Untrusted Server Certificate	If you specify a URL for the metadata provider, select this option to allow the system to download the metadata file even if the server certificate is not trusted. This is necessary only for HTTPS URLs.
Accept Unsigned Metadata	If this option is not selected, unsigned metadata is not imported. Signed metadata is imported only after signature verification.
Signing Certificate	<p>Browse and locate the certificate that verifies the signature in the metadata file. This certificate overrides the certificate specified in the signature of the received metadata. If no certificate is uploaded here, then the certificate present in the signature of the received metadata is used.</p> <p>Select the Enable Certificate Status Checking option to verify the certificate before using it. Certificate verification applies both to the certificate specified here and the certificate specified in the signature in the metadata file.</p>
Metadata Provider Filter Configuration	
Roles	Select whether the metadata file includes configuration details for a SAML service provider, identity provider, or Policy Decision Point. You may select more than one. If you select a role that is not in the metadata file, it is ignored. If none of the selected roles are present in the metadata file, the system returns an error.
Entity IDs To Import	Enter the SAML Entity IDs to import from the metadata files. Enter only one ID per line. Leave this field blank to import all IDs. This option is available only for uploading local metadata files.

The Refresh button downloads the metadata files from the remote location even if these files have not been modified. This operation applies only to remote locations; local metadata providers are ignored if selected.

To refresh a metadata file:

1. Select **System > Configuration > SAML**.
2. Select the metadata file to refresh and click **Refresh**.

To delete a metadata file:

1. Select **System > Configuration > SAML**.
2. Select the metadata file to delete and click **Delete**.

Configuring IPS as a SAML 2.0 Service Provider

This topic describes how to configure the system as a SAML service provider. When the system is a SAML service provider, it relies on the SAML identity provider authentication and attribute assertions when users attempt to sign in to the device. Note that authentication is only part of the security system. The access management framework determines access to the system and protected resources.

The system supports:

- HTTP Redirect binding for sending AuthnRequests
- HTTP Redirect binding for sending/receiving SingleLogout requests/responses
- HTTP POST and HTTP Artifact bindings for receiving SAML responses
- RequestedAuthnContext context class specifications

Before you begin:

- Check to see whether the SAML identity provider uses HTTP POST or HTTP Artifact bindings for SAML assertions.
- Check to see whether the SAML identity provider has published a SAML metadata file that defines its configuration. If the SAML identity provider metadata file is available, configuration is simpler and less prone to error.
- Complete the system-wide SAML settings if you have not already done so. Select **System > Configuration > SAML > Settings**. For details, see [Configuring Global SAML Settings](#)
- Add metadata for the SAML identity provider to the metadata provider list if you have not already done so. Select **System > Configuration > SAML**. For details, see [Managing SAML Metadata Files](#)

The sign-in URL for which a session needs to be established for the system as a service provider is identified by the RelayState parameter (HTTP URL parameter for artifact and HTML form parameter for POST.) In a service provider initiated case, the system populates RelayState as an HTTP URL parameter while sending AuthnRequest. In the IdP-Initiated scenario (Connect Secure is a service provider and there is a third-party IdP), the IdP must be configured to set the appropriate Sign-in URL of the system in the RelayState parameter of the HTML form containing the SAML response. For more information, see the SAML 2.0 specification.

To configure the system as a SAML service provider:

1. Select **Authentication > Auth. Servers**.
2. Select **SAML Server** from the New list and then click **New Server** to display the configuration page.
3. Complete the settings as described in table.
4. Save the configuration.

After you save changes for the first time, the page is redisplayed and now has two tabs. Use the Settings tab to modify any of the settings pertaining to the SAML server configuration. Use the Users tab to monitor user sessions.

Next steps:

- Configure the access management framework to use the SAML authentication server. Start with realm and role mapping rules.
- Configure a sign-in policy. When using a SAML authentication server, the sign-in policy can map to a single realm only.

Configuring a Role Mapping Rule Based on a SAML Attribute

You can use role mapping rule custom expressions to include SAML Attribute statement as a factor in role determination. IPS uses attributes from attribute statement in "User Name Template" under **Authentication > Auth. Server > SAML Server**.

To configure role mapping rules:

1. Select **Users > User Realms**.
2. Create a new realm or edit a realm you have already created.

3. Click **New Rule** to display the configuration page.
4. Select **Custom Expression** and click **Update** to redisplay the configuration page with the controls related to custom expressions.
5. Click **Expressions** to display the server catalog dialog box.

The screenshot shows a configuration window for SAML expressions. It has two tabs: 'Expressions' (selected) and 'Variables'. Under 'Expressions', there's a 'View' dropdown set to 'saml', a 'Name' field with 'saml', and a large text area for the 'Expression' containing the code `userAttr.group = "engg"`. To the right is an 'Expressions Dictionary' with a list of attributes: `time.month`, `time.year`, `user`, `userAgent`, `userAttr.<auth-attr>`, `userDN`, `userDN.<user-attr>`, `userDNText`, and `userName`. Each item has a right-pointing arrow. At the bottom left are three buttons: 'Save Changes', 'Close', and 'Delete'. At the bottom right is a dropdown menu with an equals sign and a blue button labeled '< Insert Expression'.

On SAML IdP, attributes in attribute statement can be configured as name-value pairs and/or can be fetched from directory server. For example, an attribute with name="group" and value="engg" can be configured on IdP asserts that an authenticated user belongs to engineering group. SAML assertion from IdP contains this attribute in attribute statement.

1. Select `samlAuthnContextClass`, select an operator, and click **Insert Expression**.
2. Edit the expression template to match the `AuthnContextClassRef` data expected from the SAML IdP.
3. Save your changes to the variable expression and return to the rule configuration page.

4. Select the expression, roles for the rule, and the stop option (if desired).
5. Save your changes to the rule configuration and return to the realm configuration page.
6. Reorder the rules if necessary.
7. Save the realm configuration.

Using an SQL Auth Server

This topic describes integration with the SQL Auth server.

SQL Auth Server Overview

This section describes support for using the SQL (also known as Oracle Database server) as a IPS authentication server. It includes the following sections:

Understanding SQL Auth Server

The SQL Auth server is widely deployed in the enterprise. Some enterprises use the SQL Auth server to store user credentials (usernames and passwords), MAC addresses, and other organizational information, such as group affiliations that are often the basis for authorization decisions. To support authentication and authorization against SQL Auth server databases, IPS supports an authentication server configuration that configures an Oracle Instant Client connection as well as relevant queries to the backend SQL Auth server.

Feature Support

Policy Secure uses Oracle Instant Client 11.2.0.2.0 to communicate with the SQL Auth server. The SQL Auth server version must support this version of the client. The access management framework depends on the SQL Auth server features described in this section.

You can use the SQL queries for authentication, authorization and role mapping, or both.

SQL SELECT Statements

The authentication transaction is based on an SQL query that returns a password (and possibly other information) based on the name entered by the user attempting to log in.

While a sample SQL query is provided in the original configuration file, you must configure the SQL entry of the configuration file with a query appropriate to your database. The query you enter must be either an SQL SELECT or an SQL EXECUTE statement that contains additional syntax elements that are preprocessed by the SQL authentication module.

The SQL authentication module executes SQL statements in parameterized form. This means that the SQL statement is compiled once, with parameter markers (usually question marks) as placeholders for data items that vary from one execution to the next. Only upon execution of the statement are the actual data values supplied.

The SQL statement you compose must not include parameter markers directly. Instead, include the names of the parameters where parameter markers would appear, in an appropriate format.

This is an example of a parameter marker:

1. SELECT password, profile, fullname FROM usertable WHERE username = :username
2. The SQL authentication module translates the SQL statement provided, replacing parameter names with parameter markers prior to passing the SQL statement to the database engine.
3. The SQL statement can be very simple. Basically, all that is required is to look up a password and possibly some optional information based on a username. The SQL statement can also be quite complex; it can include inner joins, and it can contain expressions. The underlying database engine is responsible for handling the SQL statement; the SQL authentication module performs no interpretation of the SQL statement other than to translate parameter names to parameter markers.

SQL Stored Procedures

A stored procedure is a sequence of SQL statements that form a logical unit and perform a task. You can use stored procedures to encapsulate a set of queries or operations that can be executed repeatedly on a database server. For example, you can code operations on an employee database, such as password lookup, as stored procedures that can be executed by application code. Stored procedures can be compiled and executed with different parameters and results. Stored procedures can use any combination of input parameters (the values passed to the stored procedure at execution time) and output parameters (the values set or returned by the stored procedure to the calling application or environment).

Vendor	Example of a called procedure
--------	-------------------------------

Oracle	BEGIN; myCalledProcedure(:username, :password!os, ipAddr!ios, filterId!o); END;
MySQL	CALL myCalledProcedure(:username, :password!os, ipAddr!ios, filterId!o);
MSSQL	{CALL myCalledProcedure(:username, :password!os, ipAddr!ios, filterId!o)}

As shown in the example, the procedure is called myCalledProcedure with input variables as username and ipAddr, output parameters as password, ipAddr, and filterId. The names of the output parameters are the names of the attributes added to the server catalog used for role mapping and return attributes. The parameter consists of a colon (:), the name of the parameter, and a format specifier.

SQL Format Specifiers

Table describes the SQL statement format specifiers with parameters in called procedures.

Specifier	Definition
i	Input parameter (Default if none is specified)
io	Input/output parameter
o	Output parameter
s	String type (default if none is specified)
n	Int type

SQL Statement Parameters

Table describes the SQL statement parameter names and types.

Item	Type	Meaning for SQL Authentication
:username	String	Specifies the username as presented to the authentication server.
:password	String	Specifies the password as presented to the authentication server.
:realm	String	Specifies the realm as presented to the authentication server.
:ipAddr	String	Specifies the source IP address (L3 authentications only), which is sent as a string. For example, 10.17.1.155.
:userAgent	String	Specifies the user agent string.

Item	Type	Meaning for SQL Authentication
:log inTime	Int	Specifies the log in time presented in the number of seconds.
:log inURL	String	Specifies the user URL of the sign-in policy of the user.
:callingStationId	String	Specifies the MAC address of the client presented as xx-xx-xx-xx-xx-xx for L3 authentications and in the format specified by the RADIUS client for L2 authentications.
:language	String	Specifies the language used by client as specified by IETF language tag. For example, en-US for English as used in the United States.

SQL Password Hash Format

Table describes the different SQL password types.

Hash/Name	Definition	Password Format	Supported RADIUS Protocols
Automatic	Automatically determines hash format based on Format.	All	
Clear Text	No Encryption	PasswordText	PAP, CHAP, MSCHAP, MSCHAP-V2, EAP-JUAC, EAP-MSCHAP-V2, EAP-MD5-Challenge
SHA 1	SHA1+Base64 hash	{SHA}HashHashHash	PAP, EAP-JUAC
Salted SHA 1	salted SHA1+Base64 hash	{SSHA}HashHashHashSalt	PAP, EAP-JUAC
NT Hash**	MD4 hash of the unicode form of password	{md4}HashHash	PAP, MSCHAP, MSCHAP-V2, EAP-JUAC, EAP-MSCHAP-V2

Interoperability Requirements and Limitations

The following limitation applies when defining and monitoring an SQL Auth server instance:

- The maximum number of connections to an Oracle database is limited to 50 connections for L2 and L3 log ins (concurrent and open RADIUS protocol), without any browser log ins.
- You must enter the SQL keywords in uppercase letters.

Configuring Authentication with an Oracle SQL Auth Server

To configure authentication with an SQL Auth server:

1. Select **Authentication > Auth.servers**.
2. Select SQL Auth Server and click New Server to display the configuration page.
3. Select the SQL Vendor as Oracle. Complete the configuration as described in
4. Save the configuration.

Auth Servers > oracle > Settings

Settings

Settings | Users

*Name: Label to reference this server.

*SQL Vendor:

*SQL Auth Server: Name or IP address

*SQL Port:

Backup SQL Auth Server: Name or IP address

Backup SQL Port:

SQL Service Name: SQL Service/Database Name

*Admin:

*Password:

*Connection Timeout: Seconds to wait for connection to SQL Auth server(Min 5, Max 120)

*Search Timeout: Seconds to wait for search results, excluding connection time(Min 5, Max 120)

*You have Agreed to the Oracle Instant Client License Agreement

▼ Finding user entries

*SQL Statement: example: SELECT password FROM usertable WHERE username = :username AND realm = :realm

Password Attribute Name: attribute from SELECT list that contains password

Full Username Attribute Name: attribute from SELECT list that contains Full User Name

SQL Password Type:

▼ Test User Lookup

Select Statement Values:

☐ Save SQL Column Names or Called Procedure variable names as Attribute names in the Server Catalog

Results:

▼ Server Catalog

* indicates required field

Settings	Guidelines
Name	Specify a name to identify the server within the system.
SQL Vendor	Select Oracle. Read and accept the license agreement. You cannot save or test the configuration until you have accepted the license agreement.
SQL Auth Server	Specify the SQL Auth server host name or IP address. The default value is 1521.
SQL Port	Specify the SQL port number through which the SQL Auth server is accessed.
Backup SQL Auth Server	(Optional) Specify the backup SQL Auth server host name.

Settings	Guidelines
Backup SQL Port	(Optional) Specify the backup SQL port number.
SQL Service Name	(Optional) Specify the SQL service name if SQL service name has been defined in the SQL Auth server configuration.
Admin	Specify the administrator username.
Password	Specify the password.
Connection Timeout	Specify the connection timeout value from 5 to 60 seconds. If this time is exceeded, and if there is a backup server defined, then the device attempts to reach the backup server.
Search Timeout	Specify the search timeout value from 5 to 60 seconds. It specifies the maximum amount of time the device will wait for the SQL Auth server to return search results.
Finding user entries	
SQL Statement	<p>Specify the SQL statement to find the user entries. For example: SELECT password FROM usertable WHERE username = :username AND realm = :realm</p> <hr/> <p> You must enter the SQL keywords in uppercase letters.</p>
Password Attribute Name	Specify the attribute name specified in the SQL statement that the device uses for password authentication. If the username that is entered exists in the database, then the authentication succeeds. If you are using the SQL Auth server for authorization, no password is necessary here.
Full Username Attribute Name	(Optional) Specify the attribute name specified in the SQL statement for the system to use when displaying the user's full name.
SQL Password Type	<p>Select one of the following SQL password types:</p> <ul style="list-style-type: none"> • Automatic • Clear Text • SHA 1

Settings	Guidelines
	<ul style="list-style-type: none"> • Salted SHA 1 • NT Hash <p>The SQL password type setting specifies the format of the hash used for the password. The values for the SQL password type include a prefix index that indicates how the password has been processed. The prefix is in clear-text between curly braces { } and is immediately followed by a hash value computed from the password. If no prefix is present in the value retrieved from the table Password column, the entire password is assumed to be in clear-text format.</p>
Test User Lookup	
Select Statement Values	Enter the attributes necessary to fill in the WHERE part of the SQL statement and click the Test Connection button to save the server configuration and attempt to connect to the database server with the information you have entered
Save SQL Column Names or Called Procedure variable names as Attribute names in the Server Catalog	Select this option to use the SQL query statement variables as server catalog attributes. You can use the server catalog in role mapping rules.
Server Catalog	
Attributes	The Attributes button appears after you have saved the server information or performed a test connection operation. Click the Attributes button to display the server catalog.

Configuring Authentication with MySQL Auth Server

To configure authentication with an SQL Auth server:

1. Select **Authentication > Auth.servers**.
2. Select **SQL Auth Server** and click **New Server** to display the configuration page.

3. Select the SQL vendor as MYSQL.
4. Complete the configuration as described in table
5. Save the configuration.

Auth Servers > MySQL > Settings

Settings Users

*Name: Label to reference this server.

Settings	Guidelines
Name	Specify a name to identify the server within the system.
SQL Vendor	Select MYSQL as the vendor type.
SQL Auth Server	Specify the SQL Auth server host name or IP address. The default value is 1521.

Settings	Guidelines
SQL Port	Specify the SQL port number through which the MYSQL Auth server is accessed. Default port is 3306.
Backup SQL Auth Server	(Optional) Specify the backup SQL Auth server host name.
Backup SQL Port	(Optional) Specify the backup SQL port number.
SQL Service Name	(Optional) Specify the SQL service name if SQL service name has been defined in the SQL Auth server configuration.
Admin	Specify the administrator username.
Password	Specify the password.
Connection Timeout	Specify the connection timeout value from 5 to 60 seconds. If this time is exceeded, and if there is a backup server defined, then the device attempts to reach the backup server.
Search Timeout	Specify the search timeout value from 5 to 60 seconds. It specifies the maximum amount of time the device will wait for the SQL Auth server to return search results.
Use SSL	Select Use SSL to establish an encrypted connection between the client and server.
Server Certificate Validation	Select this option to validate the server certificate before using the public and private keys for encryption/decryption.
Finding user entries	
SQL Statement	Specify the SQL statement to find the user entries.
Password Attribute Name	Specify the attribute name specified in the SQL statement that the device uses for password authentication. If the username that is entered exists in the database, then the authentication succeeds. If you are using the SQL Auth server for authorization, no password is necessary here.
Full Username Attribute Name	(Optional) Specify the attribute name specified in the SQL statement for the system to use when displaying the user's full name.
SQL Password Type	Select one of the following SQL password types:

Settings	Guidelines
	<ul style="list-style-type: none"> • Automatic • Clear Text • SHA 1 • Salted SHA 1 • NT Hash <p>The SQL password type setting specifies the format of the hash used for the password. The values for the SQL password type include a prefix index that indicates how the password has been processed. The prefix is in clear-text between curly braces { } and is immediately followed by a hash value computed from the password. If no prefix is present in the value retrieved from the table Password column, the entire password is assumed to be in clear-text format.</p>
Test User Lookup	
Select Statement Values	<p>Enter the attributes necessary to fill in the WHERE part of the SQL statement and click the Test Connection button to save the server configuration and attempt to connect to the database server with the information you have entered.</p> <p>Upon a successful connection and retrieval of the user record, the server displays the results. It displays the entire returned user record (hiding the password) from the SELECT portion of the SQL statement. An error line is displayed if the connection to the SQL Auth server fails or if the user record could not be retrieved. The user record is displayed in the following format: attribute Name1 = value, attribute name2 = value, and so on.</p> <hr/> <div>  <p>When trying to populate the server catalog attributes for the SQL Auth server, you must enter data into all columns of interest for a record. Columns that are not assigned data are ignored during the lookup and are therefore not added appropriately to the server catalog.</p> </div> <hr/>

Settings	Guidelines
Save SQL Column Names or Called Procedure variable names as Attribute names in the Server Catalog	Select this option to use the SQL query statement variables as server catalog attributes. You can use the server catalog in role mapping rules.
Server Catalog	
Attributes	The Attributes button appears after you have saved the server information or performed a test connection operation. Click the Attributes button to display the server catalog.

Configuring Authentication with MSSQL Auth Server

To configure authentication with an SQL Auth server:

1. Select **Authentication > Auth.servers**.
2. Select **SQL Auth Server** and click **New Server** to display the configuration page.
3. Select the SQL vendor as MSSQL.
4. Complete the configuration as described in table
5. Save the configuration.

Settings	Guidelines
Name	Specify a name to identify the server within the system.
SQL Vendor	Select MSSQL as the vendor type.
SQL Auth Server	Specify the MSSQL Auth server host name or IP address.
SQL Port	Specify the MSSQL port number through which the MYSQL Auth server is accessed. Default port is 1433.
Backup SQL Auth Server	(Optional) Specify the backup MSSQL Auth server host name.

Settings	Guidelines
Backup SQL Port	(Optional) Specify the backup MSSQL port number.
SQL Service Name	(Optional) Specify the SQL service name if SQL service name has been defined in the SQL Auth server configuration.
Admin	Specify the administrator username.
Password	Specify the password.
Connection Timeout	Specify the connection timeout value from 5 to 60 seconds. If this time is exceeded, and if there is a backup server defined, then the device attempts to reach the backup server.
Search Timeout	Specify the search timeout value from 5 to 60 seconds. It specifies the maximum amount of time the device will wait for the SQL Auth server to return search results.
Use SSL	Select Use SSL to establish an encrypted connection between the client and server.
Server Certificate Validation	<p>Select this option to validate the server certificate before using the public and private keys for encryption/decryption.</p> <hr/> <p> The server certificate validation for MSSQL is qualified using self signed certificate.</p> <hr/>
Finding user entries	
SQL Statement	Specify the SQL statement to find the user entries.
Password Attribute Name	Specify the attribute name specified in the SQL statement that the device uses for password authentication. If the username that is entered exists in the database, then the authentication succeeds. If you are using the SQL Auth server for authorization, no password is necessary here.
Full Username Attribute Name	(Optional) Specify the attribute name specified in the SQL statement for the system to use when displaying the user's full name.
SQL Password Type	<p>Select one of the following SQL password types:</p> <ul style="list-style-type: none"> Automatic

Settings	Guidelines
	<ul style="list-style-type: none">• Clear Text• SHA 1• Salted SHA 1• NT Hash <p>The SQL password type setting specifies the format of the hash used for the password. Troubleshooting Oracle Error Codes

Table describes the Oracle error codes, cause, and action.

Error code	Cause	Action
ORA-00018: maximum number of sessions exceeded	All session state objects are in use.	Increase the value of the SESSIONS initialization parameter.
ORA-00019: maximum number of session licenses exceeded	All licenses are in use.	Increase the value of the LICENSE MAX SESSIONS initialization parameter.
ORA-00020: maximum number of processes (string) exceeded	All process state objects are in use.	Increase the value of the PROCESSES initialization parameter.

Using a Time-Based One-Time Password (TOTP) Authentication Server

This topic describes IPS integration with the Time-Based One-Time Password (TOTP) Authentication

Overview

This section describes support for using the Local/Remote IPS TOTP authentication server.

Understanding TOTP

Time-based One-time Password Algorithm (TOTP) is an algorithm that computes a one-time password (token) from a shared secret key and the current time. Google Authenticator is one of such implementations of TOTP algorithms. IPS supports TOTP authentication by using the Google Authenticator algorithm for generation of shared secret key and token. Many third-party aIPS are available for almost all mobile and desktop operating systems for the generation of TOTP tokens.

Interoperability Requirements and Limitations

Before you begin:

TOTP authentication server users' configuration is automatically synchronized within all nodes in a single cluster. If there are multiple clusters behind a DNS load-balancer, then the admin has to manually perform binary export/import user's configuration to all the nodes in different clusters.

TOTP feature is configurable across clusters.

First time users have to register a new TOTP user-account via web. End-users cannot use Desktop applications and Mac applications for new user registration.

Two standalone nodes or separate clusters can be synced. For now, binary import/export of user configuration option can be used.

For the users who are already using custom sign-in pages:

For TOTP authentication to work, existing custom sign-in pages need to include following sign-in pages:

- `TotpAuthRegister.shtml`
- `TotpAuthRegister-mobile-webkit.shtml`
- `TotpAuthRegister-ipad.shtml`
- `TotpAuthRegister-stdaln.shtml`
- `TotpAuthRegister-new-ux.shtml`
- `TotpAuthTokenEntry.shtml`
- `TotpAuthTokenEntry-new-ux.shtml`
- `TotpAuthTokenEntry-mobile-webkit.shtml`
- `TotpAuthTokenEntry-ipad.shtml`

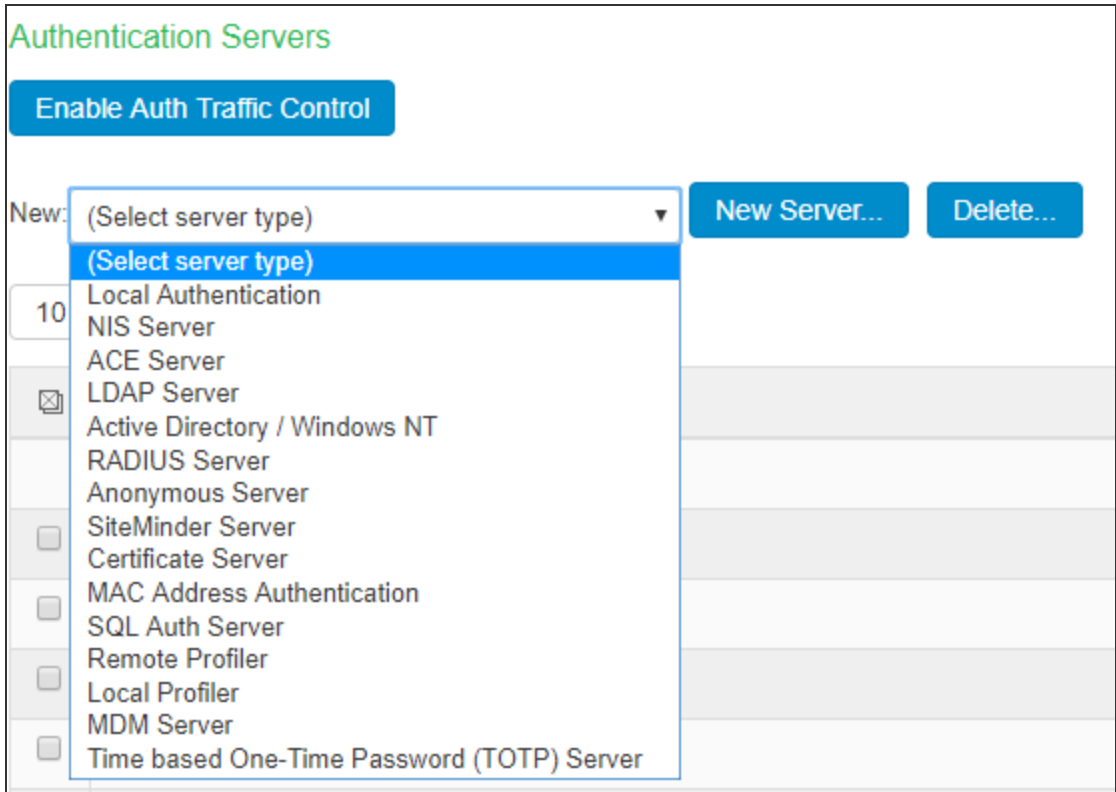

- TotpAuthTokenEntry-stdaln.html

These files can be downloaded from sample custom sign-in pages URL: <https://<IPS>/dana-admin/download/sample.zip?url=/dana-admin/auth/custompage.cgi?op=Download&samplePage=sample>

Configuring Authentication with a TOTP Authentication Server

To configure the TOTP server as Local:

1. Select **Authentication > Auth. Servers**.
2. Select **Time based One-Time Password (TOTP)** Server and click **New Server** to display the configuration page.

3. Complete the configuration as described in table.
4. Save the configuration.

Auth Servers > TOTP_Local > Settings

Settings

Settings

Users

*Name: Label to reference this server.

Server Type: ☒ Local ☐ Remote

Time Skew: minutes Max time difference between pulse secure appliance and end user device while authenticating a user's token.

Number of attempts allowed: attempts Max number of consecutive wrong attempts allowed after which account will be locked.

Custom message for registration page

You will need to install a two factor authentication application (Google Authenticator) on your smartphone or tablet.

Allow Auto Unlock ☐

Allow new TOTP user registration to happen via external port ☐ When unchecked (default), new TOTP user registrations will happen only via company intranet network

Accept TOTP authentication from remote Pulse Secure devices ☐ When checked, REST access to this TOTP server is allowed from other Pulse Secure devices.

Display QR code during user registration ☒

Disable generation of backup codes ☐

* indicates required field

Settings	Guidelines
Name	Specify a name to identify the server within the system.
Server Type	TOTP server can be configured as local or remote. Select Local. Local: TOTP context is created locally and user database is maintained locally on the same device.
Time Skew	Specify maximum time difference between IPS and end user device while authenticating a user's token. (minimum: 1 minute, maximum: 5 minutes).
Number of attempts allowed	Specify maximum number of consecutive wrong attempts allowed after which account will be locked (minimum: 1 attempt, maximum: 5 attempts).

Settings	Guidelines
Custom message for registration page	Specify a custom message which can be shown on new TOTP user registration web-page.
Allow Auto Unlock	When checked, locked account will be automatically unlocked after specified period. (minimum: 10 minutes, maximum: 90 days)
Allow new TOTP user registration to happen via external port	When unchecked (default), new TOTP user registrations will happen only via internal port
Accept TOTP authentication from remote internal devices	When checked, REST access to this TOTP server is allowed from other internal devices.
Display QR code during user registration	When checked, displays QR code during user registration.
Disable generation of backup codes	When unchecked, generates backup codes.

To configure the TOTP server as Remote:

1. Select **Authentication > Auth. Servers**.
2. Select Time based One-Time Password (TOTP) Server and click New Server to display the configuration page. See figure
3. Complete the configuration as described in table.
4. Save the configuration.

If IPS is configured to use Remote TOTP server, then the remote server should have a valid certificate issued by a Trusted CA.

Auth Servers > TOTP Remote > Settings

Settings

Settings Users

*Name: Label to reference this server.

Server Type: ☐ Local ☒ Remote

Allow new TOTP user registration to happen via external port ☐ When unchecked (default), new TOTP user registrations will happen only via company intranet network

*Host Name/IP: Remote hostname or IP where TOTP server is configured.

*TOTP Server Name: TOTP server name on remote host.

*REST API Login: REST API login name.

*REST API Password: REST API password.

*REST Authentication Realm: Realm to be used for REST Authentication

Check server reachability without saving your changes

* indicates required field

Settings	Guidelines
Name	Specify a name to identify the server within the system.
Server Type	TOTP server can be configured as local or remote. Select Remote. Remote: In this configuration, authentication check happens on the remote TOTP server. The user local device acts as a proxy between the user's client device and TOTP server. The communication to the remote device happens on REST API.
Allow new TOTP user registration via external port	Enable this option to allow TOTP user registrations through external port.

Settings	Guidelines
Host Name/IP	Specify remote host name or IP address where the TOTP server is configured.
TOTP Server Name	This is the name of the TOTP server configured on the Remote TOTP server.
REST API Login	Enter the REST API login name.
REST API Password	Enter the REST API password.
REST Authentication Realm	Enter the realm name, which refers to the realm that should be used for authenticating the rest user (using the authserver mapped to the Realm).

Configuring Admin/User Realm to Associate a TOTP Authentication Server as Secondary Authentication Server

For example, to configure a user realm:

1. Select **Users > User Realms > New User Realm**.
2. Complete the settings for the user-realm.
3. Check the Enable additional authentication server option.
4. Under Additional Authentication Server, select any already created TOTP authentication-server from the Authentication #2 dropdown, as shown in table.

Whenever admin selects TOTP authentication-server as the additional authentication server, then the Username: Predefined as <USER> and Password: specified by user in sign-in page options are set by default.

5. Click on **Save Changes**.

User Realms > Users > General

General

General Authentication Policy Role Mapping

* Name: Users Label to reference this realm

Description: Default authentication realm for users

☐ When editing, start on the Role Mapping page

▼ Servers

Specify the servers to use for authentication and authorization. To create or manage servers, see the [Servers](#) page.

Authentication: AD_200.100 Specify the server to use for authenticating users.

User Directory/Attribute: Same as above Specify the server to use for authorization.

Accounting: None Specify the server to use for Radius accounting.

Device Attributes: None Specify the server to use for device authorization.

▼ Additional Authentication Server

☒ Enable additional authentication server

You can specify an additional authentication server. The additional credentials can be specified by the user on the sign-in page (the labels for these inputs are specified by the sign-in page), or they can be pre-defined below, in which case the user will not be prompted for the credential.

☐ Enable adaptive authentication

Note: Adaptive authentication is supported by leveraging the behavioral analytics. Enable behavioral analytics on 'System->Behavioral Analytics->Configuration' for supporting this. Adaptive Authentication is not supported with 'Anonymous' type authentication server selected as authentication server above.

Authentication #2: TOTP_Server

Username is: ☐ specified by user on sign-in page

☒ predefined as: <USER>

Password is: ☐ specified by user on sign-in page

☐ predefined as: <PASSWORD> ☐ Mask static password

☒ End session if authentication against this server fails

Using [Google Authenticator](#) Application to Register to a TOTP Server

The admin can associate an end-user to a realm that has a secondary authentication server configured as TOTP authentication server.

For first time registration via web, perform the following steps:

For example: Admin associates an end-user User1 to a user-realm that has the TOTP authentication-server configured as the secondary authentication-server.

When User1 for the first time, performs a login to the above configured user-realm:

1. After successful authentication with primary authentication-server, User1 is shown the TOTP registration page. See figure

2. User1 is given a TOTP registration key in text form/QR image form and 10 backup codes. User saves 10 backup codes in a safe place for using it later during authentication when end-user device (where Google Authenticator app is installed) is not available (in emergency).
3. Now, User1 opens the device where Google Authenticator app is installed, then either scans the QR image (or) manually adds a new user (for example: GA-User1) by entering the above given secret registration key.
4. The Google-Authentication app (for GA-User1) generates a new 6-digit number called as a token once in every 30 seconds.
5. Enter the current token in the registration page. Click on **Sign In**. On successful authentication with that token, User1 will be taken to his/her home page.

Pulse Secure

**Welcome to
Pulse Policy Secure**

Add *totp-user* user account to your two factor authentication app
You will need to install a two factor authentication application (Google Authenticator) on your smartphone or tablet.

1. Configure the App:
Open your two factor authentication app and add "*totp-user*" user account by scanning the below QR code.
If you can't use QR code, then enter [this text](#)

2. Store Backup Codes:
Backup codes can be used to access your account in the event you loose access to your device and cannot receive two-factor authentication codes. Following backup codes are only for one time use, we recommend you to save them securely.

ZHQC4H	2WQM6O
FKTTYW	3WHCS5
KJRO3O	B5VGX7
JB4WSO	SPYGVO
2QEFIH	OUJEY4

Copy to Clipboard

3. Enter token code that the application generates:

For already registered user, perform the following steps:

1. The already-registered user (For example: User1), whose realm was associated with secondary authentication server configured as TOTP authentication server, accesses IPS URL via web (User1 has already registered TOTP user in Google Authenticator app.)
2. After successful authentication with primary authentication server, user1 is shown TOTP Token entry page as seen in figure
3. User1 opens Google Authentication app that was installed in mobile (or PC), enters the current token to the
4. Authentication Code. If mobile is not available, user can enter any of the unused backup codes.
5. On successful authentication with the token, User1 can enter any of the unused backup codes.

A backup code can be used only once to successfully authenticate with the TOTP authentication server. Once used, the same backup code cannot be reused.

Welcome to
Ivanti Policy Secure

Two-Factor Authentication for *totp-user*

Open the two-factor authentication app on your device to view your authentication code and verify your identity .

Currently if you do not have access to your device, use one of the backup codes saved previously.

Authentication code:

Displaying the User Accounts Table

To display user accounts:

1. Select **Authentication > Auth.Servers**.
2. Click the link for the authentication server you want to manage.

3. Click the Users tab to display the user accounts table. The Last Sign-in Statistic column shows the last successful sign-in date and time for each user, the user's IP address, and the agent or browser type and version.
 - The "Last Attempted" column shows the last time and date a user attempted to login.
 - The "Last Successful Login" shows the last successful sign-in date and time for each user.
4. Under the "User Information" column, there are details available for a user's "Realm", "Primary AuthServer" and the "Status" columns.

There are 3 possible states for the "Status" column:

- Active: TOTP user's account is in use (that is user has used this account less than stale period of this TOTP authentication server)
- Locked: TOTP user account has been locked due to maximum number of wrong login attempts
- Unregistered: TOTP user has seen registration page, but yet to complete the registration by entering the correct token in the registration page.

Use the controls to search for users and manage user accounts:

To search for a specific user, enter a username in the Show users named field and click Update.

You can use an asterisk (*) as a wildcard, where * represents any number of zero or more characters. For example, to search for all usernames that contain the letters jo, enter *jo*. The search is case-sensitive. To display the entire list of accounts again, type * or delete the field's contents and click Update.

To limit the number of users displayed on the page, enter a number in the Show N user's field and click Update.

To unlock a user, select the specific user and click **Unlock**.

To reset a user's credentials, select the specific user and click **Reset**.

Auth Servers > TOTP_Local

Viewing/Generating Backup Codes

To view/generate TOTP backup codes after successful login to a TOTP server via web:

1. User successfully authenticates to primary auth-server and TOTP auth-server via web.
2. Click on the Preference option on the top of the page.
3. In the Preference page, under TOTP Backup codes, click on either View or Generate to obtain user's TOTP backup codes.

The screenshot shows a web interface for user preferences. At the top left is a wrench icon and the title "Preferences". Below this is a "General" tab. The "Change Password" section contains three input fields: "Old Password:", "New Password:", and "Confirm Password:". To the right of the "Confirm Password:" field is a "Change Password" button. Below the "Change Password" section is the "TOTP Backup Codes" section, which includes "View" and "Generate" buttons. Below these buttons is a table of backup codes:

VRUDW5	3YGM33
WY22PA	JMHETQ
OR4ZU4	5CLOBF
KOUCBT	MEBQ46
IM6TXX	NH3PQD

At the bottom of the TOTP Backup Codes section is a "Copy to Clipboard" button.

Exporting/Importing TOTP Users

To export/import TOTP users:

1. Select **Authentication > Auth. Servers**.
2. Click the link for the authentication server you want to manage.
3. Click the Users tab to display the user accounts table. The user accounts table includes entries for the accounts that have been created.
4. Use the Export and Import buttons located at the bottom of the user accounts table to export and import TOTP users data.

Configuring HTTP Attribute Server

IPS retrieves endpoint/user information and uses it for compliance assessments and role assignment. The configured HTTP attribute server has to be mapped as a "Device Attributes" under the realm configuration and role mapping rules can be used to assign the roles based on the attributes received from the attribute server.

To configure authentication with HTTP Attribute server:

1. Select **Authentication > Auth.servers**.
2. Select **HTTP Attribute Server** and click **New Server** to display the configuration page.
3. Enter the name of the server.
4. Select the required template from the drop down.

5. Enter the hostname/IP address of the third-party server.
6. Click **Test Connection** to validate the connection between IPS and third-party server (McAfee ePo/Nozomi Networks).
7. Save the configuration.

Auth Servers > New HTTP Attribute Server

New HTTP Attribute Server

* Name: Label to reference this server.

Cascading Authentication Support

Cascading multiple external authentication servers provides a continuous, reliable process for authenticating and authorizing external users. If authentication fails on the first authentication server, then IPS attempts to authenticate the user by using the subsequent external authentication server configured in the realm under the sign-in policy page. The fallback mechanism continues until the user is successfully authenticated or there is no available realm. This feature is supported for Native Supplicant 802.1x and non EAP (like PAP, CHAP) RADIUS usecase.

To configure cascading authentication support:

1. Select **Authentication > Auth.servers** and create auth server. For example, AD or RADIUS server.

2. Select **Signing in > Sign-in Policies**. Arrange the realms in the desired order. The fallback authentication is based on this order.
3. Enable **Fallback to next available realm if authentication fails** option for user or admin users.

Signing In > Sign-in Policies > */

*/

User type: ☒ Users ☐ Administrators

Sign-in URL: Format: <host>[:<path>]. Use * as wildcard in the beginning of the host name.

Description:

Sign-in page: To create or manage pages, see [Sign-in pages](#).

▼ Authentication realm

Specify what realms will be available when signing in.

<input type="checkbox"/>	Available realms	Authentication protocol set	
	<input type="text" value="Cert Auth"/>	<input type="text" value="- Not applicable -"/>	<input type="button" value="Add"/>
<input type="checkbox"/>	adrealm	802.1X	
<input type="checkbox"/>	ldaprealm	802.1X	
<input type="checkbox"/>	localrealm	802.1X	
<input type="checkbox"/>	sbrrealm	802.1X	
<input type="checkbox"/>	sqlrealm	802.1X	

If more than one realm appears above, the Policy Secure sign-in page will ask the user to choose. Other endpoints cannot choose a realm; the Policy Secure will assign the first suitable realm from the list. If no realms appear above, sign-in will fail.

☒ Fallback to next available realm if authentication fails

☐ User may specify the realm name as a Username suffix

4. Verify the Sign-in Policies page.

Signing In > Sign-In Policies

Sign-In Policies

Sign-In Policies | Sign-In Pages | Sign-In Notifications | Authentication Protocol Sets

☐ Restrict access to administrators only

Only administrator URLs will be accessible across the cluster. Note that Administrators can attempt to sign in even if all rules on this page are disabled.
Warning: Enabling this option will immediately terminate all user sessions from all nodes across the cluster.

Configuring MSSQL Server Accounting

IPS supports storing the RADIUS accounting information to an external SQL database. IPS offers SQL Accounting feature under Auth Servers. MSSQL accounting supported only for 802.1x use cases and only one SQL server can be configured.

- The SQL statement is completely user-specified, allowing support of existing tables with existing field names and formats. It can include a variety of arithmetic and string expressions.
- Stored procedures invoked by SQL accounting can make use of input parameters, record results, and return output parameters.

Radius Accounting Request (Start, Stop, Interim) is received in IPS from switch. Radius Accounting attributes are extracted, and the attributes configured in the SQL queries will be sent to the SQL server based on the realm configuration. Apart from RADIUS Accounting Request attributes, the attributes in the below table can also be used in the insert query.

Attribute Name	Datatype	Description
TransactionTime	Time	The date/time that the event occurred that is the subject of the request.
Time	Time	The date/time when the request is being processed. (This is later than TransactionTime if the request is a retry.)
Type	String	The RADIUS accounting request type.
NASAddress	IP address	The IP address of the requesting RAS.
NASName	String	The name of the network access device that originated the request. This may be the name of the RADIUS client entry in the database or the value of the NAS-Identifier or NAS-IP-Address attribute.
NASModel	String	The RAS make/model.
FullName	String	The full name of the logged in user.
AuthType	String	The method by which the user was authenticated.

Attribute Name	Datatype	Description
RADIUSClientName	String	The name of the network access device, as specified in a RADIUS client entry in the Steel-Belted Radius database.

Configuring SQL Accounting

You must configure both IPS and SQL database to support SQL accounting.

1. Select **Authentication > Auth.Servers** and select **SQL Auth Server**.
2. Select **Accounting** in configure SQL server.
3. Enter the SQL Accounting server settings as described in the table in the following steps.
4. Under SQL Accounting Queries, enable Use this Acct-Start statement for Acct-Stop and Acct-Interim to use the same Start statement for Acct-Start and Acct-Interim.

5. Click **Test Connection** to test the connectivity to the server.

6. Click **Save Changes**.

Settings	Guidelines
Name	Specify a name to identify the server within the system.
SQL Accounting Server	Specify the SQL Accounting server host name or IP address.
SQL Port	Specify the SQL port number through which the SQL Accounting server is accessed.
SQL Service Name	(Optional) Specify the SQL service name if SQL service name has been defined in the SQL Accounting server configuration.
Admin	Specify the administrator username.
Password	Specify the password.
Connection Timeout	Specify the connection timeout value from 5 to 60 seconds. If this time is exceeded, and if there is a backup server defined, then the device attempts to reach the backup server.
Search Timeout	Specify the search timeout value from 5 to 60 seconds. It specifies the maximum amount of time the device will wait for the SQL Accounting server to return search results.
Use SSL	Select Use SSL to establish an encrypted connection between the client and server.
Server Certificate Validation	Select this option to validate the server certificate before using the public and private keys for encryption/decryption.

7. Under **User Realms > Users**, select the SQL Accounting server.

AUT31643	2021-07-01 09:11:16 - ic - [10.96.202.1] PPSQ@%hmi (Users) - IP Address 10.00.002.1 has been released for the user PPSQ@%hmi
EAM24805	2021-07-01 09:11:16 - ic - [127.0.0.1] PPSQ@%hmi (Users) - RADIUS authentication accepted for PPSQ@%hmi (realm 'Users') from location-group 'Default' and attributes are: NAS-IP-Address = 10.0.0.3.41, NAS-Port = 2, NAS-Port-Type = 15

The following is an example of a SQL INSERT statement in IPS-SQL Accounting query. The insert statement will directly provide the attributes and value placeholders to be saved on the SQL database.

For SBR-E customers, the "%" and "@" symbols in the insert query should be replaced with ":" symbol and the format specifiers should be removed.

```
INSERT INTO shrisql_start("Acct-Session-Id", "Acct-Status-Type", "Service-Type", "Acct-Authentic", "NAS-Port", "Calling-Station-Id", "Called-Station-Id", "NAS-Port-Type", "NAS-IP-Address", "NAS-Identifier", "User-Name", "MS-RAS-Vendor", "Acct-Delay-Time", "Framed-IP-Address", "TransactionTime", "Time", "NASAddress", "NASName", "NASModel", "FullName", "AuthType", "RADIUSClientName") VALUES (:Acct-Session-Id, :Acct-Status-Type, :Service-Type, :Acct-Authentic, :NAS-Port, :Calling-Station-Id, :Called-Station-Id, :NAS-Port-Type, :NAS-IP-Address, :NAS-Identifier, :User-Name, :MS-RAS-Vendor, :Acct-Delay-Time, :NASAddress, :TransactionTime, :Time, :NASAddress, :NASName, :NASModel, :FullName, :AuthType, :RADIUSClientName)
```

Stored Procedure Example

The following is an example of stored procedure configuration to insert an entry to the SQL table.

```
{CALL shrisql_start_sp(:Acct-Session-Id, :Acct-Status-Type, :Service-Type, :Acct-Authentic, :NAS-Port, :Calling-Station-Id, :Called-Station-Id, :NAS-Port-Type, :NAS-IP-Address, :NAS-Identifier, :User-Name, :MS-RAS-Vendor, :Acct-Delay-Time, :NASAddress, :TransactionTime, :Time, :NASAddress, :NASName, :NASModel, :FullName, :AuthType, :RADIUSClientName)}
```

Stored Procedure syntax on MSSQL Server

The following is an example of a stored procedure syntax on MSSQL server.

```
CREATE PROCEDURE shrisql_start_sp
(
    @AcctSessionId varchar(40), @AcctStatusType varchar(40), @ServiceType varchar(40), @AcctAuthentic varchar(40),
    @NASPort varchar(40), @CallingStationId varchar(40), @CalledStationId varchar(40), @NASPortType varchar(40), @NASIPAddress varchar(40),
    @NASIdentifier varchar(40), @UserName varchar(40), @MSRASVendor varchar(40), @AcctDelayTime varchar(40), @FramedIPAddress varchar(40),
    @TransactionTime varchar(40), @Time varchar(40),
    @NASAddress varchar(40), @NASName varchar(40), @NASModel varchar(40), @FullName varchar(40), @AuthType varchar(40), @RADIUSClientName varchar(40))
AS
BEGIN
    SET NOCOUNT ON

    INSERT INTO shrisql_start ([Acct-Session-Id], [Acct-Status-Type], [Service-Type], [Acct-Authentic], [NAS-Port], [Calling-Station-Id],
    [Called-Station-Id], [NAS-Port-Type], [NAS-IP-Address], [NAS-Identifier], [User-Name], [MS-RAS-Vendor], [Acct-Delay-Time], [Framed-IP-Address],
    [TransactionTime], [Time],
    [NASAddress], [NASName], [NASModel], [FullName], [AuthType], [RADIUSClientName])
    VALUES (@AcctSessionId, @AcctStatusType, @ServiceType, @AcctAuthentic, @NASPort, @CallingStationId,
    @CalledStationId, @NASPortType, @NASIPAddress, @NASIdentifier, @UserName, @MSRASVendor, @AcctDelayTime,
    @FramedIPAddress, @TransactionTime, @Time,
    @NASAddress, @NASName, @NASModel, @FullName, @AuthType, @RADIUSClientName)
END
```

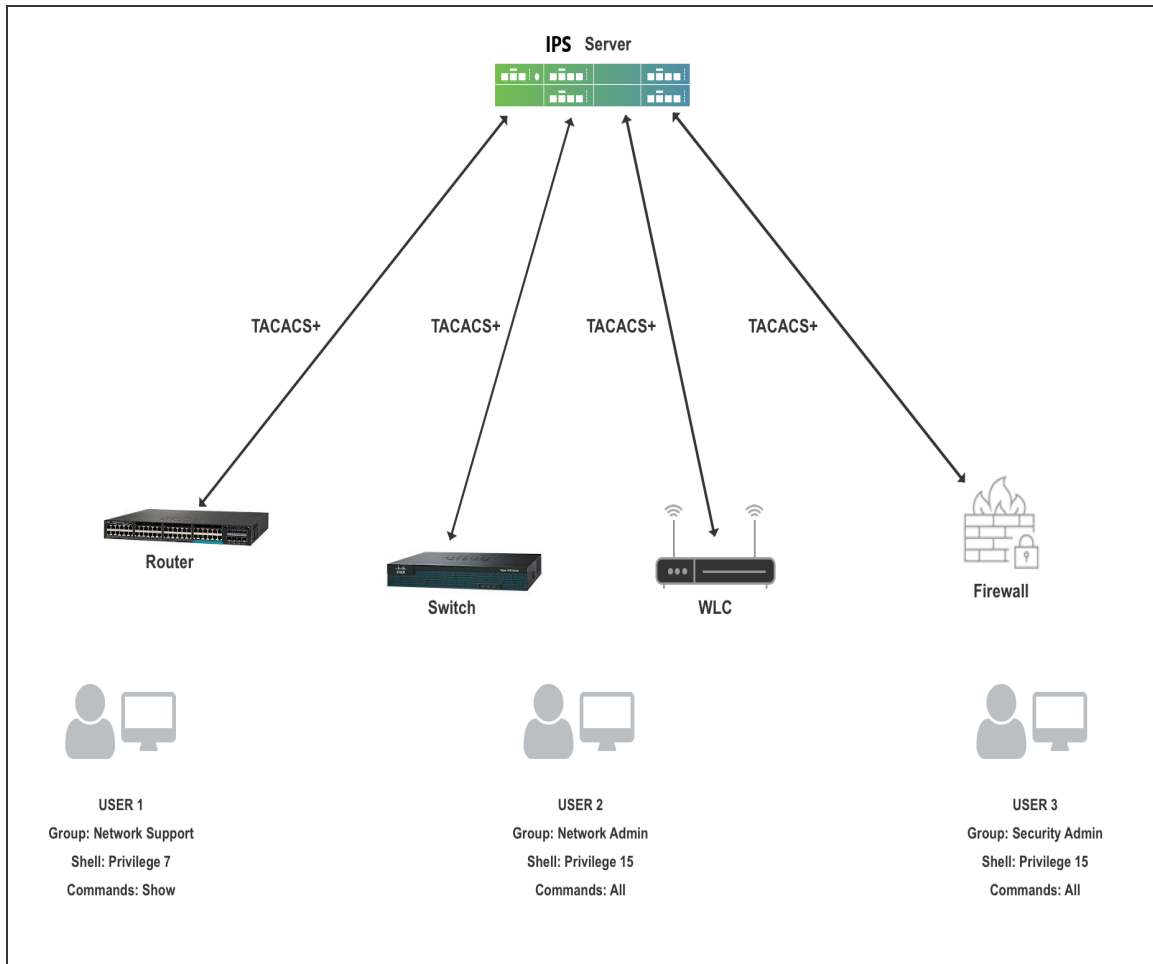

Network Device Administration using TACACS+

Overview

The network device administrators are required to configure and maintain the network devices such as switches, wireless access points, routers, and gateways. IPS supports configuring and coordinating the network devices through IPS Admin UI.

The administrator implements policies to determine who can login to a network device console, telnet session, secure shell (SSH) session to manage each device, what level of privilege do they have, what operations they can run (that is, the commands the admin user is permitted to run on the device) and also audit all the actions taken.

Managing these policies separately on each device is not just unmanageable but can lead to security incidents or errors that result in loss of service and network downtime due to undesired access. Most compliance requirements and security standards require using standardized tools to centralize authentication for administrative management.

The above deployment consists of 3 types of administrators:

- **User1** - This admin belongs to Network Support Group and can only access show commands on router, switches and access points. The admin has no access to Firewall.
- **User2** - This admin belongs to Network Admin Group and can access all commands on routes, switches and access points. The admin has no access to Firewall.
- **User3** - This admin belongs to Security admin group and an firewall administrator and does not have access to routers, switches and access points.

A large company will have many devices from different vendors. It requires administrators to manage the network with many hierarchical levels.

Without a centralized server for administration, every time a new device is deployed, several admin accounts need to be created on the new device to assign the required privilege for each of the admin. Similarly, if a new admin onboards an functional organization, the account needs to be created on thousands of devices.

With Ivanti Policy Secure(IPS) acting as a centralized server for device administration using TACACS+, a new admin can just be mapped to required group. A new Admin account can be configured either locally on IPS or any external servers such as AD, LDAP and so on. Similarly, when a new device is purchased, the only configuration is configuring IPS as a centralized server for device administration on device.

Licensing

TACACS+ user login does not consume any user license however either POLSEC license or Profiler license is required to be installed.

Authentication

Provides complete control of authentication through login and password.

Authorization

Provides fine-grained control over user capabilities for the duration of the user's session, which includes idle time-out, session duration. You can enforce restrictions on what commands a user may execute by configuring the privilege level for administrators. Within the privilege-level, further control can be forced by specifying command or regex match.

Ivanti Policy Secure(IPS) supports 2 types of authorization techniques for administrators:

- Exec authorization- This determines a user's privilege level when they are authenticated. The admins can run the commands, which are allowed in the user's privilege level.

- Command authorization- TACACS+ command authorization provides centralized control of the commands available to IPS admin user. In this, every command is sent to IPS for authorization and command is permitted after getting authorized by IPS.
 - A Telnet, SSH, or console interface user who is previously authenticated by IPS using TACACS+ enters a command on the device.
 - The network device looks at its configuration to see if the command is at a privilege level that requires TACACS+ command authorization.
 - If the command requires authorization, the device consults the IPS to see if the user is authorized to use the command.
 - If the user is authorized to use the command, the command is executed.

Accounting

Collects and sends information used for auditing to the TACACS+ server. Network device administrators can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop, executed commands.

Configuration

Configuring Admin Role

Admin role enables you to define granular administrative access privileges. For example, an organization would require multiple admin roles with different privilege levels to ensure protection from sensitive company information.

To create an Admin role for TACACS+:

1. Select **Administrators > Admin Roles > New Admin Role**. Enter a role name. You can create multiple admin roles with different privilege levels. For example, tac_admin_role.

Configuring Admin Realm

An authentication realm defines the authentication server with which end user is authenticated and the list of restrictions that must be satisfied on the client machine during sign-in. It also provides role mapping option to administrators for configuring the list of roles that needs to be assigned to the user. Role mapping provides flexibility to administrators in configuring how different set of roles need to be assigned to the user.

An admin can configure multiple admin realms when different authentication servers are required for authentication for different devices. Admin's can also use different backend servers for managing different device groups.

Create an Authentication realm and then associate the authentication server to it.

1. Select **Administrators > Admin Realms > New Authentication Realm**.
2. Under Servers, specify the Authentication server (AD, LDAP, Local, or RSA (ACE Server)). For more information, see AAA Servers.

i Role mapping rule execution is based on the order of the rules.

Configuring Device Group

The device groups are created in a heterogeneous network where there are devices from multiple vendors with different command set. Devices with same command syntax are grouped so that it is easy to manage. IPS considers each group as a single unit while applying the shell policies.

For example, if your deployment has devices from multiple vendors, you can group them into multiple device groups based on their command syntax. Similarly, you can also create different device groups based on whether the device is a WLC/Switch.

To create a device group:

1. Select **Endpoint Policy > Network Device Administration > Device Group**.
2. Enter the name and description of the device group
3. Associate the previously created Admin Realm with the device group.
4. A device group policy logically groups network devices by associating the devices with specific admin realm.
5. Click **Save Changes**.

Configuring TACACS+ Client

A TACACS+ client policy specifies the information required for the device to connect to Ivanti Policy Secure for admin access control. You can add the network devices as TACACS+ clients for the administrator to manage. IPS allows you to configure an IP address range for TACACS+ clients.

To create a TACACS+ client:

1. Select **Endpoint Policy > Network Device Administration > TACACS+ Clients > New TACACS+ Client**.
2. Enter a name for the TACACS+ client.
3. Enter a description.

4. Enter the IP address of the client.
5. Enter the IP address range for the TACACS+ clients.
6. Enter the shared secret.
7. Select the device group from the drop down.
8. Under TACACS+ Advance Settings, enable/disable allow authorization without authentication.
9. Click **Save Changes**.

* indicates required field

Ivanti Policy Secure(IPS) does not support adding IPv6 TACACS+ clients.

Configuring Shell Policies

Define the Policies for the Admin Role and the corresponding Device Group. The Policies should be mapped with the selected Admin Roles and the Device Group.

To configure shell policies:

1. Select **Endpoint Policy > Network Device Administration > Shell Policies**.
2. Enter the name of the policy.
3. Enter the description.
4. Under Device Group, select the **Device Group**.
 - **Policy Applies to all groups**- If you select this option, the shell policy is applied to all the device groups.
 - **Policy Applies to selected groups**- If you select this option, the shell policy is applied only to the selected device group.
5. Under Shell Policy, specify the following:
 - Enter the Default Privilege level.
 - Maximum Privilege level (1-15).
 - (Optional) Service- The default value is "shell". Admin can explicitly configure specific service type.
6. Under Command Set, Enter the command, arguments, and the action (permit/deny) for the Admin. If it doesn't match any rule it takes the default action:
 - **Deny** any command that does not hit any of the rule
 - **Permit** any command that does not hit any of the rule
7. Command authorization is supported on most of the switches such as HP and Cisco. However, devices such as F5 and Juniper does not support individual command authorization with TACACS+ server due to the delay in command execution. For F5 and Juniper devices the required set of commands are mapped to different roles locally as the roles are predefined. The TACACS+ server sends the desired role through the custom attributes during user authentication.

Under **Custom Attributes**, enter the Attribute name, value, and specify the requirement as either mandatory or optional. Click **Add**.

Mandatory arguments require that the client must understand the attribute and act upon it otherwise the authentication fails.

8. Under Roles, select the Admin Role.

- **Policy Applies to all roles-** If you select this option, the shell policy is applied to all the admin roles.
- **Policy Applies to selected roles-** If you select this option, the shell policy is applied only to the selected admin role.
- **Policy Applies to all roles other than the selected role-** If you select this option, the shell policy is applied to all the admin roles other than the selected role.

9. Click **Save Changes**.

TACACS+ Command Sets

Command sets consists of a specific list of commands that can be executed by a network device administrator. IPS determines whether the administrator is authorized to execute these commands based on the privilege level configuration.

Regex (Wildcards)

A command line comprises the command and zero or more arguments. When IPS receives a command line (request), it handles the command and its arguments in different ways. It matches the command in the request with the command specified.

For example, Show device-[a-z]* st[a-z]*us

This command has 2 arguments.

- Argument 1 – device-[a-z]*
- Argument 2 – st[a-z]*us

The command arguments in the request are taken based on the order. After the command and arguments match to any of the command set based on the order corresponding action (permit/deny) is taken by IPS.

If command doesn't match with the any of the command set configured then default action will be taken. The default action taken can be:

- Deny any command that does not hit any of the rule
- Permit any command that does not hit any of the rule

Multiple command Sets

Ivanti Policy Secure(IPS) checks all the commands in the command set sequentially for the first match.

It compares the command name from the network device with the exact command configured in the command set.

If the command matches and there are no arguments from device group

- If there are no arguments to match from device as well as no arguments configured, then the command set is considered as match.
- If there are no arguments from device group but arguments are configured, then it's a no match.
- If arguments are sent by device group, then it is compared with regex pattern configured in arguments of the command set.

If argument is matched, then command set is considered as a match, and corresponding action is taken.

- If the first match has action as Permit, IPS designates the command set as Permit.
- If the first match has Deny, IPS designates the command set as Deny.

If the command doesn't match with any of the command set configured one of the below default action is taken.

Ivanti Policy Secure(IPS) checks all the commands in the command set sequentially for the first match.

- Deny any command that does not hit any of the rule.
- Permit any command that does not hit any of the rule.

If there are many profiles, then the first matching profile is applied.

Monitoring Device Administration

Ivanti Policy Secure(IPS) provides various logs that allow you to view information related to accounting, authorization, and command accounting of devices configured with TACACS+.

General recommendation – For recovery purposes, it is suggested to have a local backup account. The console login should be redirected to local.

To monitor device administration:

Select **System > Log Monitoring > Admin Access**:

- To enable Accounting, you must click the checkbox for **TACACS+ Accounting messages**.
- To enable authorization, you must click the checkbox for **TACACS+ Authorization messages**.

Log/Monitoring > Admin Access > Log settings

Troubleshooting

Ivanti Policy Secure(IPS) provides logging and monitoring capabilities to help you track events and user activities. The system generates event logs related to system performance, administrator actions, network communications, access management framework results, user sessions, and so forth.

The available logs, includes:

- **Event Logs-** This file contains a variety of system events, such as session timeouts, systems errors and warnings, server restart notifications and connectivity requests.
- **Admin Access Logs-** This file contains administration information, including administrator changes to user, system and network settings, such as changes to session timeouts, license changes and so on.

TACACS+ Event and Admin Logs

Event Logs

1. Logging when count of TACACS+ connection reached system limit.

Minor – Limit of <max count> TACACS+ concurrent users reached

Minor	TAC31628	2018-01-31 14:40:48 - ic - [127.0.0.1] System()[] - Limit of 2 TACACS+ concurrent users reached
-------	----------	--

2. Dropping the incoming TACACS+ connection because received from unknown host.

Major - TACACS+ request received from unknown TACACS+ client <switch IP>

Major	TAC31629	2018-01-31 14:37:54 - ic - [127.0.0.1] System()[] - TACACS+ request received from unknown client 10.204.89.239
-------	----------	--

3. Dropping the incoming TACACS+ connection due to shared-secret mismatch.

Minor - Invalid TACACS+ packet from <switch IP>, discarding.

Minor	TAC31628	2018-01-31 14:35:58 - ic - [127.0.0.1] System()[] - Invalid TACACS+ packet from 10.204.89.239, discarding. Incorrect shared secret
-------	----------	--

Admin Access Logs

1. Exec Authorization [Only when Authorization is enabled under authorization setting]

- Log for exec authorization success

TACACS+ Shell authorization successful for <user> on switch-<switch ip> and attributes are: privilege = %d, idle-timeout = %d, session-timeout = %d

Info	TAC31611	2018-01-30 18:59:03 - ic - [xx.xxx.xx.xxx] tac_user(tac_admin_realm) [tac_admin_role] - 'TACACS+ Shell authorization successful for tac_user on 10.204.89.239 and attributes are: privilege = 15, idle-timeout = 5, session-timeout = 60'
------	----------	---

- Log for exec authorization failure due to no shell policy assigned to roles.

TACACS+ Shell authorization rejected for <user> on switch-<switch ip>. Reason- %s

Reasons-

- No session found
- No Shell policy found for the assigned roles

Info	TAC31612	2018-01-30 19:06:45 - ic - [xx.xxx.xx.xxx] tac_user(tac_admin_realm)[tac_admin_role] - 'TACACS+ Shell authorization rejected for tac_user on 10.204.89.239. Reason: No Shell policy found for the assigned roles'
------	----------	---

2. Command authorization [Only when Authorization is enabled under authorization setting]

- Log for command authorization success.

TACACS+ Authorization successful for command-%s from <user> on switch-<switch ip>

Info	TAC31611	2018-01-30 19:08:14 - ic - [xx.xxx.xx.xxx] tac_user(tac_admin_realms)[tac_admin_role] - 'TACACS+ Authorization successful for command-'show version' from tac_user on 10.204.89.239'
------	----------	--

- Log for command authorization failure due to no shell policy assigned to roles or due to deny under command set.

TACACS+ authorization rejected for command-<cmd> from <user> on switch-<switch ip>. Reason- %s

Reasons-

- No session found
- No Shell policy found for the assigned roles

Info	TAC31612	2018-01-30 19:37:02 - ic - [xx.xxx.xx.xxx] tac_user(tac_admin_realm)[tac_admin_role] - 'TACACS+ authorization rejected for command-'show version' from tac_user on 10.204.89.239. Reason- No session found'
------	----------	---

- Matched with the rule – [command = %s, Arguments = %s, action = %s] in shell policy-%s

Appendix

The following example shows how to configure the switch to authenticate and account using TACACS+.

Output 1: Example: Cisco iOS

```

**Authentication
aaa authentication login default group <group-name> local
aaa authentication enable default group <group-name> enable
**Authorization
aaa authorization exec default group <group-name> local
aaa authorization commands <privilege no.> default group <group-name>
local
aaa authorization config-commands
**Accounting
aaa accounting exec default start-stop group <group-name>
aaa accounting commands <privilege no.> default start-stop group
<group-name>
aaa accounting send stop-record authentication failure

```

**Mapping TACACS+ server IP to group

```
aaa group server tacacs+ <group-name>
server-private <server-ip> key <shared-secret>
```

Output 2: Example: HP switch

```
tacacs-server host <host-ip> key <shared-secret>
aaa authentication telnet login tacacs
aaa authentication telnet enable tacacs
aaa authentication login privilege-mode
aaa accounting exec start-stop tacacs
```

HP switches should be set with privilege level always. Enable authentication is not supported.

Output 3: Example: Juniper Switch

```
root@ex-2200# show system login
class class1 {
    idle-timeout 20;
}
class network-admin {
    idle-timeout 10;
}
user network-admin {
    uid 2002;
    class network-admin;
}
user remote-read-only {
    full-name "User template for remote read-only";
    uid 2014;
    class read-only;
}
user remote-super-users {
    full-name "User template for remote super-users";
    uid 2013;
    class super-user;
}
#show system tacplus-server
<IPS-IP> {secret "fkfljsfjsafjsaf"; }
#show system accounting
events [events];
#show system tacplus-options
```

```
service-name shell;
```

For more information on Juniper, see Juniper documentation.

Output 4: Example: F5 Device

Label	Sample Configuration
TACACS+ Authentication	https://support.f5.com/csp/article/K8811  Configure Service Name as "shell" instead of "ppp" under configuration for TACACS+ authentication.
TACACS+ Accounting	https://support.f5.com/csp/article/K13762
Remote Role configuration using Custom attributes	https://devcentral.f5.com/Portals/0/Cache/Pdfs/2807/tacacs-remote-role-configuration-for-big-ip.pdf

Output 5: Example: Arista Switch

```
tacacs-server host <IPS-IP Address> key <secret-key>
!
aaa group server tacacs+ <group-name>
    server <IPS-IP Address>
!
aaa authentication login default local group tacacs+ group <group-name>
Required for enabling service authentication.
aaa authentication enable default group tacacs+ group <group-name>
local
aaa authorization exec default local group tacacs+ group <group-name>
aaa authorization commands all default local group tacacs+ group
<group-name>
aaa accounting exec default start-stop group tacacs+ group <group-name>
aaa accounting commands all default start-stop group tacacs+ group
<group-name>
For Command based Authorization configure the following command.
```

```
aaa authorization commands all default group tacacs+ group <group-name>
```

For Role based Authorization configure the following command.
configure aaa authorization commands all default local

From the IPS Admin UI configure the custom attribute for Role based authorization as shown below.

Two-Factor Authentication using Smart Cards

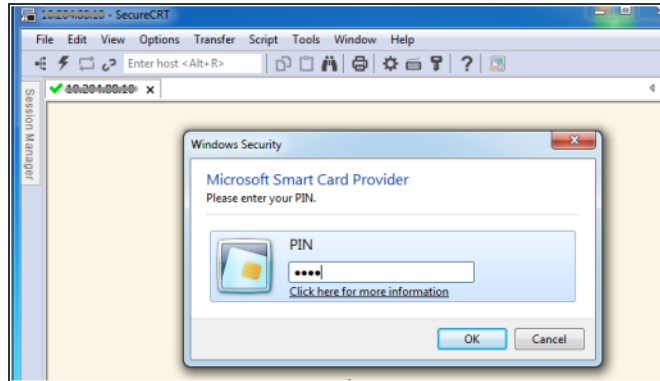

With growing digital world, effectively combating cybersecurity threats has become a major challenge. The scale and robustness of cyberattacks has been increasing rapidly. Sensitive and confidential information are getting comprised across the network due to such attacks. To combat this threat, enterprises are taking mitigating actions to strengthen device access across their critical IT infrastructure.

Two-factor authentication significantly reduces the risk of adversaries penetrating strategic networks and systems. This approach requires the use of a Personal Identity Verification (PIV) card or Common Access Card (CAC). In this document, we will detail the basic procedures required to enable two-factor authentication for the Secure Shell Protocol (SSH) using government-issued PIV or CAC cards.

The authentication process is described below:

1. User starts SecureCRT client, enters the Cisco switch IP address in the hostname and press Enter.
2. A dialog box pops up prompting for PIN. User enters the PIN associated with the smartcard credential and press OK.

3. SecureCRT forwards certificate to Cisco Switch which validates Certificate handshake.
4. Cisco switch sends TACACS+ authorization request to IPS with username set to "common name" received from certificate and "service=pki"
5. IPS fetches the role and device group based on username and realm information.
6. If a shell policy has same role, device group with mandatory attribute set to "cert-application=all", then it is considered a match. If action is set to Permit, then IPS sends successful response containing all configured attributes.
7. User gets logged in to Cisco switch.

Pre-Requisites

- Cisco switch
- Ivanti Policy Secure Release 9.1R4 as TACACS+ Server
- SecureCRT (8.5.4) as the SSH client
- Smart Card Reader
- Common Access Card

Summary of Configuration

Configuring Ivanti Policy Secure

On IPS Server Administration UI, Admin configures:

- Admin Role
- Admin Realm
- TACACS Device group
- TACACS client
- Shell policy

To configure TACACS+ client and shell policy on IPS:

1. Select **Endpoint Policy > Network Device Management > TACACS+ client**, enable **Allow Authorization (w/o authentication)** under TACACS+ Advance Settings.

[Network Device Administration](#) > [TACACS+ Client](#) > New TACACS+ Client

New TACACS+ Client

▼ TACACS+ Client

* Name:	<input type="text"/>	Label to reference this TACACS+ Client.
Description:	<input type="text"/>	
* IP Address:	<input type="text"/>	IP Address of this TACACS+ Client.
* IP Address Range:	<input type="text" value="1"/>	Number of IP Addresses for this TACACS+ Client
* Shared Secret:	<input type="text"/>	TACACS+ shared secret
* Device Group:	<input type="text" value="Default"/>	To manage groups, see the Device Group

▼ TACACS+ Advance Settings

Allow Authorization (w/o authentication)	<input type="checkbox"/>	Allow Authorization (w/o authentication)
--	--------------------------	--

[Save Changes](#)

* indicates required field

2. Select **Network Device Management > Shell Policies**.
3. Under **Custom attributes**, configure "*cert-application=all*" as mandatory attribute.
4. Click **Add**.
5. Click **Save Changes**.

The screenshot shows the TACACS+ configuration interface. The 'Custom Attributes' section is expanded, showing a table with columns: Attribute, Value, Requirement, and Action. A red box highlights the row where the Attribute is 'cert-application', the Value is 'all', and the Requirement is 'Mandatory'. Below this, there are sections for 'Rules' and 'Roles'.

Attribute	Value	Requirement	Action
cert-application	all	Mandatory	Add

Cisco Switch Configuration

1. Set up Network Time Protocol (NTP) with the proper time zone for the device This step is critical for the operation of the public key infrastructure (PKI).

```
service timestamps debug datetime msec localtime show-timezone
service timestamps log datetime msec localtime show-timezone
clock timezone EST -5 0
clock summer-time EDT recurring
ntp server <server ip>
```

2. Configure PKI trustpoint for the certificate authority (CA). Specify the field from the user certificate that will be used as the SSH username that will pass to the TACACS server for authorization. The example below uses the common name from the subnet field for the username. The user principal name (UPN) from the Subject-Alternative name can also be used as a username for SSH login.

```
crypto pki trustpoint <trustpoint name>
enrollment terminal
revocation-check none
authorization username subjectname commonname
```

3. Manually authenticate and install the root CA's public certificate.

```
crypto pki authenticate <trustpoint name>
```

4. Generate RSA signing and encryption keys for the SSH server.

```
crypto key generate rsa modulus 2048 label SSH-RSA usage-keys
```

5. Enable the SSH server and specify the RSA keys to be used for signing and encryption.

```
ip ssh rsa keypair-name SSH-RSA
ip ssh version 2
```

6. Configure the Cisco IOS SSH server to verify the user's X.509v3 digital credential for two-factor authentication.

```
ip ssh server certificate profile
  user
    trustpoint verify <trustpoint name>
    ip ssh server algorithm hostkey ssh-rsa
    ip ssh server algorithm authentication publickey
    ip ssh server algorithm publickey x509v3-ssh-rsa
```

7. Enable SSH for terminal line access, and enable X.509v3 validation.

```
aaa new-model
!
line vty 0 4
  login authentication default
  transport input ssh
```

8. Add the TACACS+ server and provision the shared secret and IP address of the TACACS+ server.

```
tacacs server IPS
  address ipv4 <server-ip>
  key <encryption key>
```

9. Configure TACACS+ for user authorization.

```
aaa group server tacacs+ IPS
  server name IPS
aaa authorization config-commands
aaa authorization exec IPS group tacacs+
aaa authorization commands 0 IPS group tacacs+ if-authenticated
aaa authorization commands 1 IPS group tacacs+ if-authenticated
aaa authorization commands 15 IPS group tacacs+ if-authenticated
aaa authorization network IPS group tacacs+
aaa authorization configuration IPS group tacacs+
```

10. Enable authorization on the PKI trustpoint CA for the user certificate.

```
crypto pki trustpoint <trustpoint name>
  authorization list IPS
```

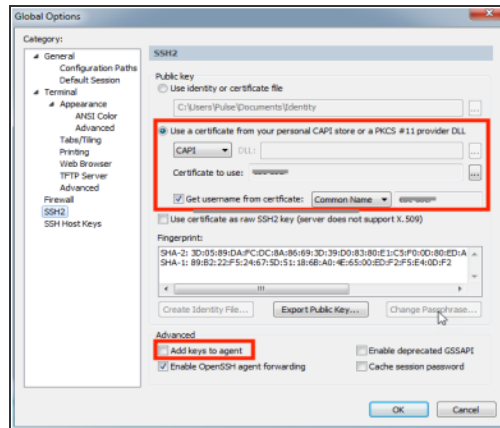

Configuring SecureCRT Client for Two-Factor Smartcard Authentication

If your SSH2 server environment is properly configured for X.509 smartcard certificate authentication, then you can configure SecureCRT/SecureFX to authenticate using Two-Factor Authentication certificates on your smartcard.

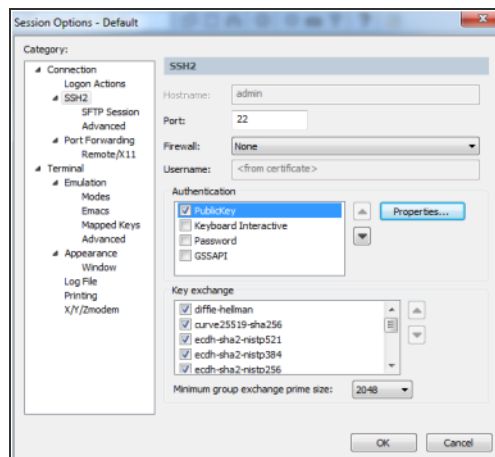

To configure SecureCRT/SecureFX for Windows to accomplish authentication using your smartcard:

1. Start the SecureCRT client. Open **Global Options** and select the **SSH2** category.
2. In the **Public key** section, enable **Use a certificate from your personal CAPI store or a PKCS #11 provider DLL** option.
3. Insert your smartcard.
4. For the **Certificate to use** field, press the [...] button to the right and browse through the available certificates.
5. If your certificate contains the user account name that should be used for authentication, enable the **Get username from certificate** option. Then specify the certificate field which contains the account name required for smartcard authentication to your SSH2 servers (either **Principal Name** or **Common Name**).

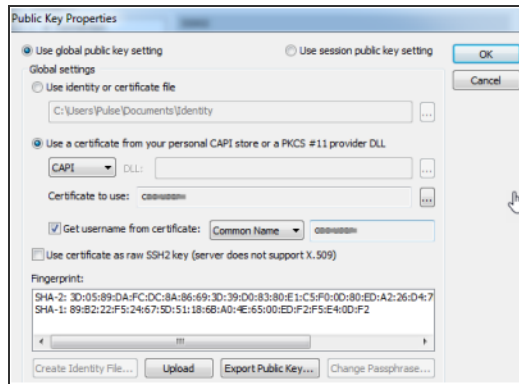

- Disable the **Add keys to agent** option in the **Advanced** section below the fingerprint viewing area.

- Click **OK** to save changes.
- Choose **Options > Edit Default Session...**
- Select the **SSH2** category. In the Authentication list, highlight the **PublicKey** authentication method and move it to the top of the list.
- With **PublicKey** selected, press **Properties...** button.

- In the Public Key Properties window, enable the Use global public key setting option. Information should match what was specified in the Global Options settings above.

12. Press **OK** button to close the **Public Key Properties** window
13. Press **OK** button to close the **Session Options** window.
14. When prompted for selecting Apply default session changes, choose either of the option. If smartcard certificate will be authenticated for the majority of connections, then consider selecting Change ALL sessions (no undo).

As configured above, SecureCRT do not cache smartcard PIN. The first time user authenticate with a certificate on the smartcard, user will be prompted for the PIN by MS CAPI or your smartcard's middleware provider. If subsequently user is not prompted for PIN when authenticating with the smartcard, it is because PIN has been cached by smartcard's middleware.

Guest Access

Overview

Ivanti Policy Secure(IPS) provides guest access management solution through which you can manage and secure your guest network access.

Ivanti Policy Secure(IPS) supports the following mechanisms for guest access management:

- Guest Access through Guest User Account Manager (GUAM)
- Self-Registration
- Sponsor Approved Guest Access

Guest User Account Manager (GUAM)

The guest users use their own devices to access internet. A guest account can be created by a guest admin (GUAM) such as a receptionist. The GUAM user has below guest administration capabilities:

- Create temporary guest access accounts for guest users
- Create bulk accounts for numerous guest users
- Notify guest user credentials through email or text message.

Self-Registration

The guest self-registration enables a guest to access a Self-Registration URL and create their own guest account for internet access. The username and password for a self-provisioned guest account is delivered directly to the guest's web browser, or sent via SMS or email.

The self-registration workflow is described below:

1. The user connects to wireless network through guest SSID.
2. The user tries to access internet.
3. WLC redirects the user to IPS guest sign-in URL.

4. The user performs self-registration and signs-in through the credentials.
5. If the authentication is successful, the guest user can access internet.

Sponsor Approved Guest Access

The sponsor approved guest access provides access to the guest user only if it is approved by the Guest Sponsorer. The Sponsorer validates the guest user before giving the required access. This feature provides additional security by providing access only to valid guest users. The Sponsor takes the responsibility for the actions of the Guest and thus it brings accountability for the network usage and enhances the security of the network.

The sponsored guest access workflow is described below:

1. The Guest user connects to wireless network through guest SSID.
2. The Guest user performs the self-registration and the guest account will be created in disabled state and the access request is sent to the Sponsor (Employee/GUAM).
3. The Sponsorer will receive an email notification about the new guest access request.
4. The Sponsorer logs in to the Sponsor portal and approves/denies the guest user.
5. If the Sponsor approves the request the guest account becomes active and an email/SMS notification is sent to guest about activation of the account. If sponsor denies the request, the guest account will be deleted and an email/SMS notification is sent to guest about deny access.

Deployments

This topic describes the deployment scenarios of the Guest access solution.

Guest Access using WLC

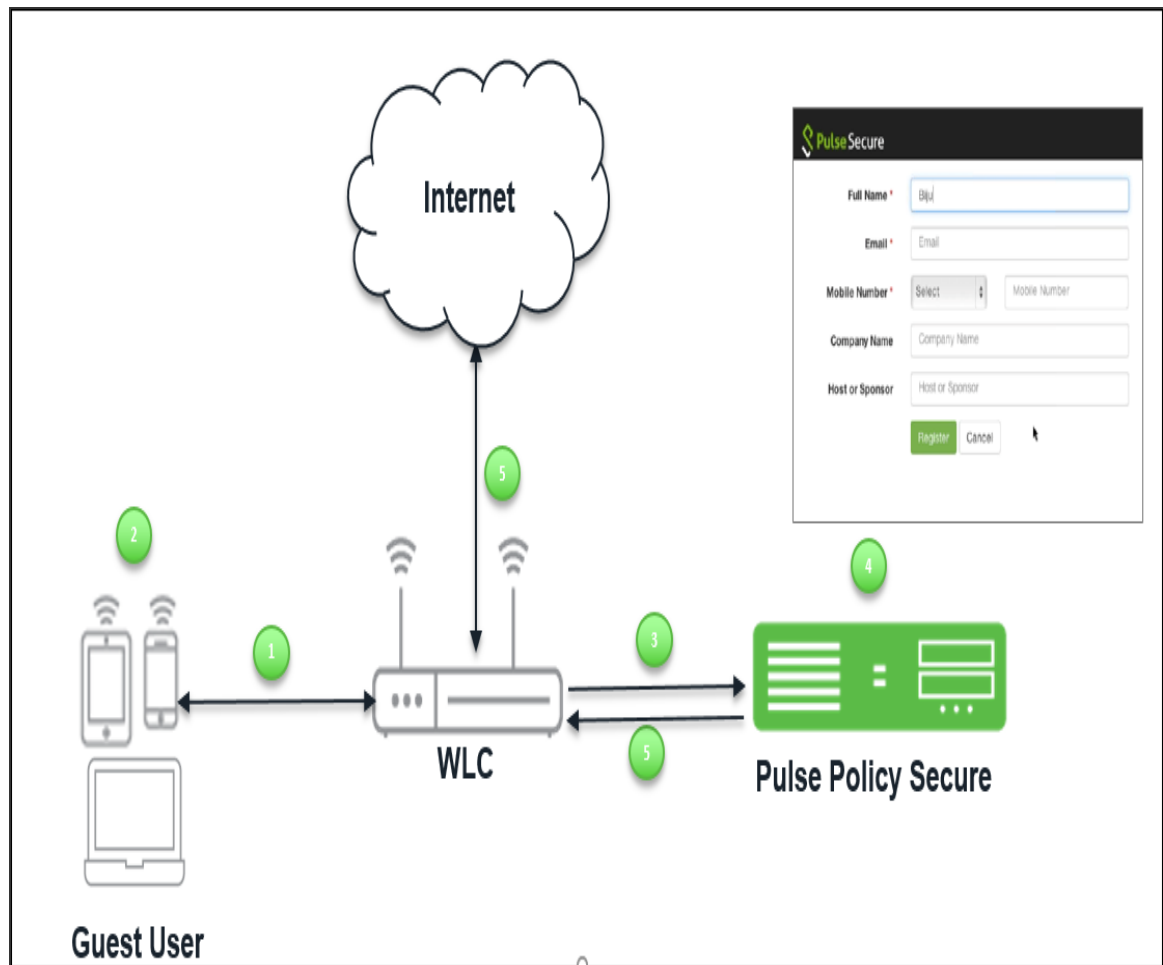

The guest access solution for wireless network can be deployed with leading Wireless LAN controllers. You can deploy wireless network with WLCs and wireless network for guests. The guest authentication is done with external authentication server and IPS server can be used as an external authentication server.

The assumption for this deployment the user has already deployed wireless network for guest using WLC and would like to have centralized authentication server. When wireless network is built with multiple vendors WLCs then it further becomes useful to have centralized authentication server.

The user flow is explained below:

1. Guest user comes on-premises and connects to guest SSID.
2. Guest user opens a browser to access an internet resource.
3. The user is redirected to IPS guest login page.
4. Guest user clicks the self-registration link from the guest login page and completes the registration process.
5. If the Administrator has configured Host Checker policy then IPS evaluates the Host Checker results.
6. Pre authentication – Host Checker policies are evaluated first and then user is prompted for credentials. For configuration details, see [User Realms](#)
7. Post authentication – User credentials are validated first and then the Host Checker policies are evaluated. For configuration details, see [User Roles](#)
8. Guest user logs in with guest user credentials. IPS validates the credentials and based on the

result WLC redirects the guest user to the resource requested.

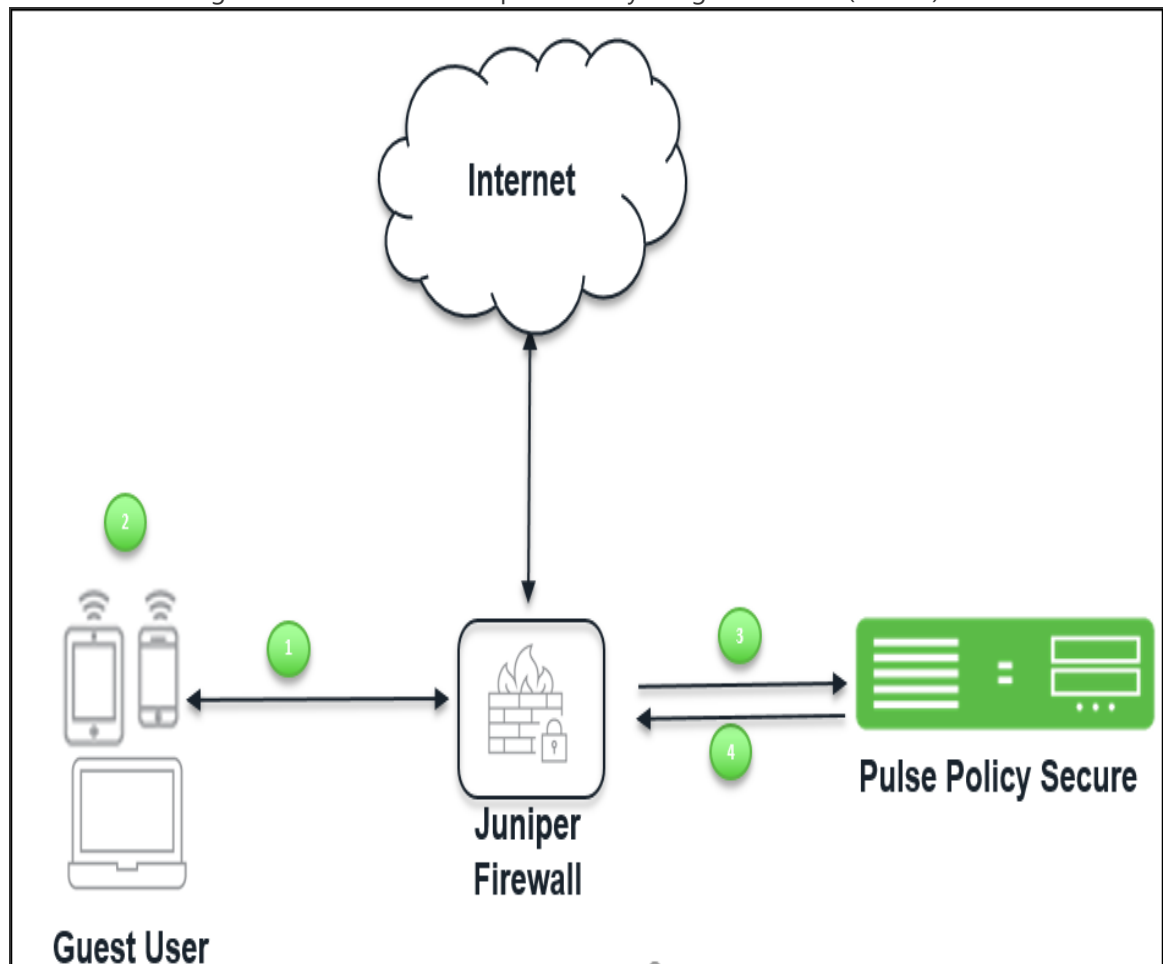

Guest Access using EX switch/SRX Firewall

When a IPS and an EX Series switch/SRX firewall is deployed, users must first sign into IPS for authentication before they can access a protected resource behind the EX Series switch/SRX firewall.

To facilitate sign-in, you can configure a redirect policy on the EX Series switch/SRX firewall to automatically redirect HTTP traffic destined for protected resources to IPS. When the sign-in page for the IPS is displayed, the user signs in, and access is granted to internet. These user accounts can be created by Guest User Account Manager.

The user flow is explained below:

1. Guest user comes on-premises and tries to connect to internet.
2. Guest user opens a browser to access an internet resource.
3. The Guest user is redirected to IPS login page.
4. If the Admin has configured Host Checker restrictions on the Guest role/realm then the Guest user is provided access only after Host Checker policies are evaluated.
5. The Admin can configure the Host Checker in two ways:
6. **Pre-Authentication (Host Checker restriction on guest realm)**– The Host Checker policies are evaluated first and then user is prompted for credentials.
7. **Post-Authentication (Host Checker restriction on guest role)** – The user credentials are validated first and then the host checker policies are evaluated.
8. The Guest user logs in with the credentials provided by the guest Admin (GUAM).

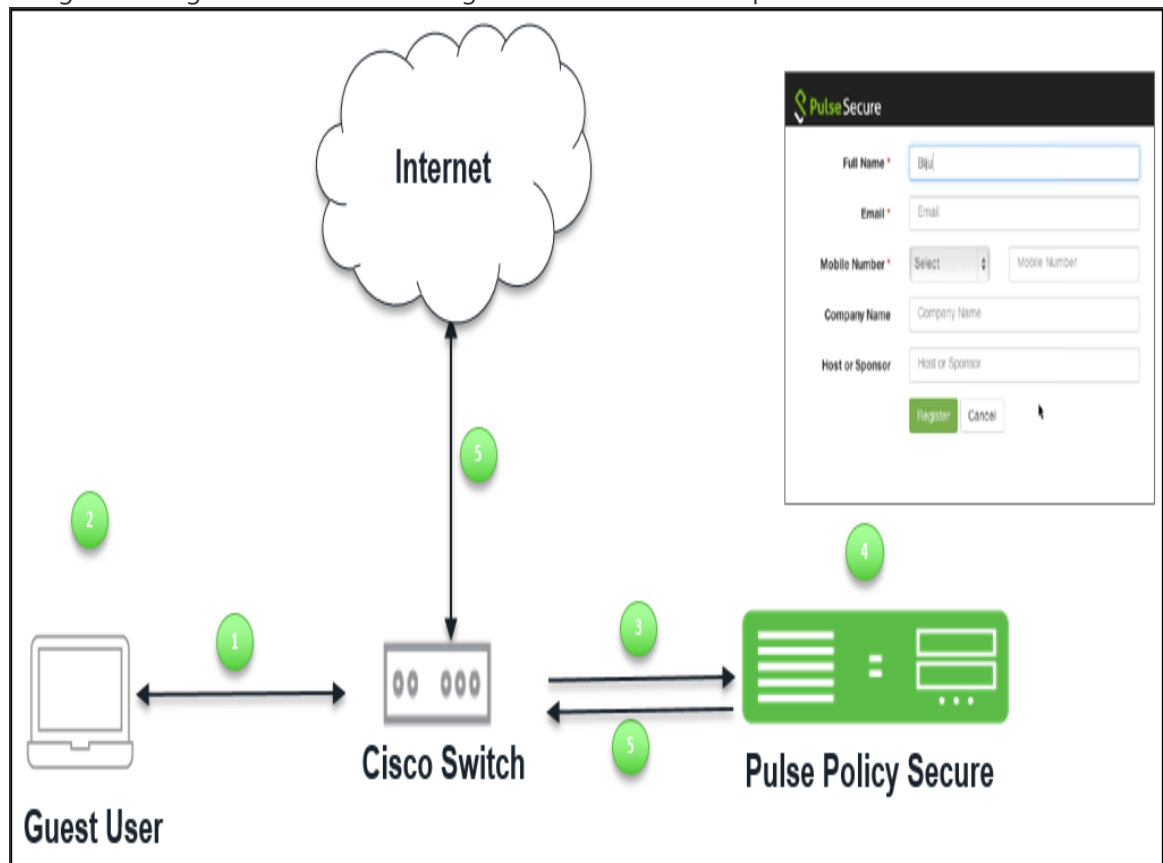

Guest Access using Cisco Switch

The guest access feature is supported for wired guest endpoints with Cisco switches. To facilitate sign-in, you can configure a redirect policy on the Cisco switch to automatically redirect HTTP traffic destined for protected resources through IPS . When the sign-in page for the IPS is displayed, the user signs in, and access is granted to internet.

The user flow is explained below:

1. Guest user comes on-premises and connects to LAN.
2. Guest user opens a browser to access an internet resource.
3. The user is redirected to IPS guest login page.
4. The Guest user self registers on IPS guest portal and receives the credentials over the email/SMS or on the UI.
5. If the Administrator has configured Host Checker policy then IPS evaluates the Host Checker results.
6. **Pre authentication** – Host Checker policies are evaluated first and then user is prompted for credentials. For configuration details, see User Realms.
7. **Post authentication** – User credentials are validated first and then the Host Checker policies are evaluated. For configuration details, see User Roles.

8. The guest user gets authenticated and gets redirected to the requested internet resource.

The configuration details are covered in [Configuring IPS for Guest Wired Authentication using Cisco Switch](#).

Configuring IPS for WLC Deployment

This section describes the configuration that is required on IPS to communicate with a Wireless LAN Controller (WLC) for Guest user management.

Ivanti Policy Secure(IPS) server acts as RADIUS server that allows to centralize the authentication and accounting for the users. You can add Cisco, Aruba, or Ruckus WLC as a RADIUS client on IPS. Guest user Self-Registration options need to be configured in the authentication server used for managing guest accounts and in sign-in policy settings.

Default Configurations for Guest Access

Ivanti Policy Secure(IPS) has some default configuration settings for convenience of the Admin users.

The default settings are:

- Sign-in Policies
- User Realms
- User Roles
- Location Groups
- Authentication Protocol Sets
- Authentication Server

Sign-In-Policies

The `*/guestadmin/`, `*/guest/`, and `*/guestsponsor` are the default Sign-in-Policies in IPS. A Sign-in Policy is mapped with a default Authentication Realm.

To view the Sign-in-Policies:

1. Select **Authentication > Signing In > Sign-in Policies**. The Sign-in Policies screen appears.

Signing In > Sign-in Policies

Sign-in Policies

Sign-in Policies | Sign-in Pages | Sign-in Notifications | Authentication Protocol Sets

☐ Restrict access to administrators only
Only administrator URLs will be accessible. Note that Administrators can attempt to sign in even if all rules on this page are disabled.
Warning: Enabling this option will immediately terminate all user sessions.

User Roles

The Guest Admin, Guest, and Guest Sponsor are the default user roles in IPS. A user realm is mapped with a default Role.

To view a User Role:

1. Select **Users > User Roles**. The Roles screen appears.

The screenshot shows the 'New Role' configuration screen. At the top, there is a breadcrumb 'User Roles > New Role' and a green heading 'New Role'. Below this, there are two input fields: 'Name:' with the value 'Full Access' and 'Description:' which is empty. A green section header 'Options' with a downward arrow is followed by a paragraph: 'Session and appearance options are specified in [Default Options](#). Check the following if this role should override these defaults.' Below this are six checkboxes: 'Session Options' (checked), 'UI Options' (checked), 'Odyssey Settings for Access' (unchecked), 'Odyssey Settings for Preconfigured Installer' (unchecked), 'Enable Guest User Account Management Rights' (unchecked), and 'Enable Sponsored Guest User Account Management Rights' (unchecked). At the bottom left is a blue 'Save Changes' button.

2. Click on a default Guest Role to view the settings.

3. The **General > Overview** screen appears. You can make necessary changes and click **Save Changes** to save the settings.

The screenshot shows the 'Overview' screen for the 'General' tab. The interface includes a top navigation bar with 'General', 'Agent', and 'Agentless' tabs. Below this is a sub-navigation bar with 'Overview', 'Restrictions', 'Session Options', and 'UI Options'. The main content area contains a form for editing the 'Users' role. The 'Name' field is set to 'Users' and the 'Description' field is set to 'System created Users role.'. A 'Save Changes' button is located below the description field. Below the form is a section titled 'Options' with a green heart icon. It contains a note: 'If these settings are not specified by any roles assigned to the user, the settings specified in Default Options will be used.' There are four options listed: 'Session Options' (checked), 'UI Options' (checked), 'Enable Guest User Account Management Rights' (unchecked), and 'Enable Sponsored Guest User Account Management Rights' (unchecked). Each of the first two options has an '(Edit)' link next to it. A 'Save Changes' button is located at the bottom left of the options section.

Configuring SMTP and SMS gateway settings on IPS

The SMTP and SMS configuration settings must be configured to enable guest users to create user accounts on their own.

SMTP Settings for Guest User Accounts

To configure the SMTP settings:

1. Select **System > Configuration > Guest Access > SMTP Settings**. The SMTP Settings screen appears.

The screenshot shows the 'SMTP Settings' configuration page. At the top, there is a breadcrumb trail: 'Configuration > Guest Access > SMTP Settings'. Below this, the page title 'SMTP Settings' is displayed. A navigation bar contains tabs for 'Licensing', 'Pulse One', 'Security', 'Certificates', 'DMI Agent', 'Sensors', 'Client Types', 'SAML', 'Guest Access' (which is highlighted), 'Advanced Networking', and 'Notification'. Under the 'Guest Access' tab, there are two sub-tabs: 'SMTP Settings' (active) and 'SMS Gateway Settings'. The main content area is divided into two sections: 'General SMTP Settings' and 'Guest Access Settings'. The 'General SMTP Settings' section includes a toggle for 'Email Account Details' (set to 'Enabled'), input fields for '*SMTP Server:' (with a hint 'IP Address or hostname of the SMTP server'), 'SMTP Login:' (with a hint 'Required if the server requires credentials to relay'), 'SMTP Password:' (with a hint 'Required if the server requires credentials to relay'), '*SMTP Email:' (with a hint 'Default email address used to send emails and receive bounce-back messages'), a toggle for 'Use SSL' (set to 'Enabled'), and '*SMTP Port:' (set to '25' with a hint 'Port to be used for SMTP server.'). The 'Guest Access Settings' section includes instructions to 'Enter settings to modify Guest User Account Manager and Guest Self-Registration features. The SMTP settings to send account details to guest via email.' It features an '*Email Subject:' input field (with a hint 'Subject to use') and an '*Email Format:' section with radio buttons for 'html' (selected) and 'text' (with a hint 'Content type to set in the email header. The default template page is in HTML (this can be changed using Custom Pages)'). A 'Save Changes' button is located at the bottom left of the form.

2. Under General SMTP settings:
 - Enter the host name or IP address of the SMTP server.
 - Enter the SMTP login name.
 - Enter the SMTP password.
 - Enter the SMTP email address.

3. The Use SSL option supports the SMTP port 587.

4. Under Guest Access Settings:
 - Enter the email subject.
 - Select the email format- html, text.
5. Click **Save Changes**.

SMS Gateway Settings for Guest User Accounts

Short Message Service (SMS) is delivered through an SMS gateway service that supports HTTP, HTTPS, and SMTP (Simple Mail Transport Protocol) delivery. You need to subscribe to an external service to be able to deliver guest details using SMS. The SMS gateway sends SMS in formatted text message using HTTP/HTTPS interface (SMS message) and can also allow email message to be sent as an SMS. An example of an SMS gateway is clickatell.com. You should have a valid account with this third party.

To create an account with Clickatell:

1. Go to http://www.clickatell.com/products/sms_gateway.php, and choose the appropriate API sub-product (connection method) you wish to use.
2. Click on the registration hyperlink.
3. Select the Account type you would like to use (Local or International).
4. Enter your personal information to complete the registration form.
5. Accept the Terms & Conditions.
6. Click Continue - An email containing your log in details such as account log in name, password, and clientID will be sent to the email address you have provided.
7. Activate your account – When user has logged in, and user will be on the Clickatell Central landing page and HTTP API will be added to the account and client API ID will be issued to the account. A single account may have multiple API IDs associated with it.

Ivanti Policy Secure(IPS) integration with Clickatell

To enable the SMS gateway settings for Clickatell:

1. Select **System > Configuration > Guest Access > SMS Gateway Settings**. The SMS Gateway Settings screen appears.

SMTP Settings **SMS Gateway Settings**

Enter settings to modify Guest User Account Manager and Guest Self-Registration features.

The SMS gateway settings to send account details to guest via SMS.

▼ **SMS Gateway Settings**

Enable SMS Gateway Settings: ☒

*SMS Gateway Type: Clickatell API Use "Clickatell API" for accounts that use "api.clickatell.com" as

*SMS Gateway URL: api.clickatell.com

*API product ID: 1234 Required if the server requires credentials to relay

*SMS Gateway Login Name: Required if the server requires credentials to relay

*SMS Gateway Password: Required if the server requires credentials to relay

Source Mobile Number: Select Require "two-way" number

Save Changes

2. Select the **Enable SMS Gateway Settings** check box.
3. Complete the configuration settings as described in table.
4. Click **Save Changes**.
5. Select the **Country** and enter the mobile number. Click **Send Test SMS**.

Settings	Guidelines
SMS Gateway Settings	
SMS Gateway Type	Select the gateway type:

Settings	Guidelines
	Clickatell Platform- Select this option to send SMS as a text message. Use "Clickatell Platform" for accounts that use "platform.clickatell.com" as gateway. Clickatell API- Select this option to send SMS as a text message. Use "Clickatell API" for accounts that use "api.clickatell.com" as gateway. Clickatell Email2SMS – Select this option to use email format as an SMS using SMTP.
API product ID	Specify the API product ID that you received from Clickatell during account creation.
SMS Gateway Login Name	Specify the SMS gateway login name.
SMS Gateway Login password	Specify the SMS gateway login password.
Text Message (SMS) Format	(Optional) Select the following fields: Guest Account Start Time Guest Account End Time Guest Account Sign-in URL Wireless SSID
The following options apply if you select Clickatell Platform as gateway type.	
SMS Gateway URL	Specify the SMS Gateway URL. (Default) https://api.clickatell.com or http://api.clickatell.com
HTTPS	Select this option to use a secure connection. If you don't select this option user will be notified about clear text transmission of guest user credentials.
Use Proxy Server	Select this option to access the internet or SMS gateway URL using a proxy server.
Address	Specify the address of the proxy server and its port.
Username	Specify the username of the proxy server.
Password	Specify the password of the proxy server.

Settings	Guidelines
Send Test SMS	
Mobile Number	Select the country name and then specify a valid phone number of the guest user. The phone number should not include country code or any special character such as +, *, and so on. The IPS sends a test SMS with the login credentials to this mobile number through SMS.
Source Mobile Number	Specify the sender ID configured in Clickatell Account

Ivanti Policy Secure(IPS) integration with EasiSMS

Ivanti Policy Secure(IPS) integrates with EasiSMS through the SMTP server. EasiSMS uses an email format to send SMS to end user mobile phones.

Ensure SMTP server is configured to use the EasiSMS feature.

To configure the SMS gateway settings for EasiSMS on IPS:

1. Select **System > Configuration > Guest Access > SMS Gateway Settings**.
2. The SMS Gateway Settings screen appears.

SMTP Settings SMS Gateway Settings

Enter settings to modify Guest User Account Manager and Guest Self-Registration features.

The SMS gateway settings to send account details to guest via SMS.

▼ SMS Gateway Settings

Enable SMS Gateway Settings: ☒

*SMS Gateway Type: EasiSMS ▼

*Domain Name: Specify domain name (For example: pulsesecure.net, google.com)

*Email Subject: Subject to use for the email

Text Message(SMS) Format(Optional Fields):

☐ Guest Account Start Time

☐ Guest Account End Time

☐ Guest Account Sign-In URL

☐ Wireless SSID

Save Changes

▼ Send Test SMS?

Mobile Number: Select ▼ Send Test SMS

3. Select Enable SMS Gateway Settings check box.
4. Select the SMS Gateway Type as EasiSMS.
5. Enter the Domain Name provided by EasiSMS.
6. Enter the unique ID in Email Subject provided by EasiSMS.
7. Optionally configure Text Message Format.
8. Click **Save Changes**.

When a guest user registers on the guest portal, the user receives an SMS with the login credentials that allows the user to access the resources.

Configuring Guest Access Settings on IPS

To configure guest access settings on IPS:

1. Select **Authentication** > **Auth. Servers** > **System Local** > **Settings**.

2. Under Guest Access Configurations:

- Select the check box **Enable Guest User Account Managers** to administer Guest Accounts.
- Under the Guest Self-Registration select Send guest user credentials via
 - SMS
 - Email
 - Click the SMS/Email settings link and do the necessary settings.
- Show credentials on screen after guest completes registration
- Maximum Account Validity Period for Self Registered Guest – Default is 24 hours. You can change this as per the requirement.
- For Sponsored Guest Access, select Enable Sponsored Guest Access.

Self-Registration is supported only with WLC deployment.

Guest Self-Registration

Send guest user credentials via: ☐ SMS ☒ Email [Configure SMS/Email settings](#)

☒ Show credentials on screen after guest completes registration

☒ Enable Sponsored Guest Access

Response message for the Sponsor:

A guest has requested access naming you as the sponsor. Please approve/deny this request at <url>.

This message will be sent as email to the sponsor.

Approve message for the Guest:

Welcome!!! Your access has been approved, please login now.

This message will be sent as email/SMS to the guest user.

Deny message for the Guest:

Your access has been rejected. Please contact your sponsor for further steps

This message will be sent as email/SMS to the guest user.

☒ Maximum Account Validity Period for Self Registered Guests: Set the Guest Account length limit in hours. This is valid for self registered guests. Does not impact existing user expirations.

Note: To enable Guest Self-Registration navigate to Signing In > Sign-in Policies > User URLs > [url] > [Configure Guest Settings](#)

3. Select **Authentication > Signing In > Sign-In Policies**.

New Sign-In Policy

User type: ☐ Users ☒ Administrators

Sign-in URL: Format: <host>[<path>]; Use * as wildcard in the beginning of the host name.

Description:

Sign-in page: To create or manage pages, see [Sign-In pages](#).

Authentication realm

Specify how to select an authentication realm when signing in.

☒ **User types the realm name**
The user must type the name of one of the available authentication realms.

☐ **User picks from a list of authentication realms**
The user must choose one of the following selected authentication realms when they sign in. If only one realm is selected, it is automatically used (the sign-in page will not display the list). To create or manage realms, see the [Administrator Authentication](#) page.

Available realms:

Selected realms:

Configure Signin Notifications

☐ Pre-Auth Sign-in Notification

☐ Post-Auth Sign-in Notification

4. Select the sign-in policy that is created earlier.

Under Configure Guest settings select the check boxes:

- Use this sign-in policy for Guest and Guest admin to use specific pages
- Show Guest Self Registration link on the guest log in page.

5. The Register as Guest link appears on the guest log in page.

Configuring IPS for SRX/EX Deployment

The Administrator must follow the below procedure for enabling guest access using SRX firewall:

- Default Configurations for Guest Access
- Configuring SMTP and SMS Gateway
- Configuring Guest Access Settings on IPS.

To configure captive portal:

1. From IPS admin UI, select **Endpoint Policy > Infranet Enforcer > Connection** and add **SRX/EX**.

Infranet Enforcer > Connection > New Infranet Enforcer

New Infranet Enforcer

▼ Infranet Enforcer

Platform: JUNOS SRX Platform of this Infranet Enforcer.

* Name: Label to reference this Infranet Enforcer.

* Password: Connection password.

* Serial number(s): One per line.

Location Group: Guest To manage groups, see the [Location Group](#)

▼ Coordinated Threat Control

Note that not all enforcer versions and platforms have an IDP module.

☐ Use IDP Module as Sensor

Save Changes

2. From the SRX CLI configuration menu, configure a captive portal named guests that redirects the unauthenticated traffic to guest URL. For example <https://xyz.abc.local/guest>.
3. Create a new policy that redirects any source that attempts to access the server.
4. You can also create Host Checker restrictions on the Guest realm/role.

Configuring IPS for Guest Wired Authentication using Cisco Switch

This section describes the configuration that is required on IPS to communicate with a Cisco switch for Guest wired authentication.

To configure IPS for guest wired authentication:

1. Select **Authentication > Auth. Servers**. The Authentication Servers screen appears.

Authentication Servers

New: (Select server type) ▼ New Server... Delete...

10 ▼ records per page Search:

Authentication/Authorization Servers	Type
Administrators	Local Authentication
Certificate Authentication	Certificate Server
Guest Authentication	Local Authentication
Guest Wired Authentication	MAC Address Authentication
System Local	Local Authentication

2. Click **Guest Wired Authentication** available by default to view the settings.

Auth Servers > Guest Wired Authentication > Settings

Settings

Settings Users

Name: Label to reference this authentication.

MAC Addresses

Maximum 500 addresses

Delete  

MAC Address	Action	Attributes	
<input type="text"/>	Allow	<input type="text"/>	<input type="button" value="Add"/>
 *.*.*.*.* .*.*.*.*	Allow		

Example MAC Address:
00:11:85:bb:8c:66
00:##:***
Example Attribute:
attribute1=value1;attribute2=value2;
(for attribute: alphanumeric or "_" or ":" characters only)
The Allow & Attributes action accepts the defined MAC Address
expression and looks it up in the optional LDAP Server(s)
below for authorization attributes.

Optional LDAP Servers

Available LDAP Servers: (none)

Selected LDAP Servers: (none)  

To manage servers, see the [Server](#) configuration page.

Server Catalog

The attributes catalog should be used for both attributes defined in the MAC Addresses Table and the optional LDAP Servers.

3. You can make the necessary changes and click **Save Changes**.

4. Select **Users > User Roles**. The User Roles page appears.

User Roles > Roles

Roles

10. Configure the RADIUS return attributes for Guest Wired policy. The RADIUS return attributes are required for moving the endpoint to the appropriate VLAN.

Network Access > RADIUS Return Attributes Policies

RADIUS Return Attributes Policies

RADIUS Dictionary | RADIUS Vendor | Location Group | RADIUS Client | **RADIUS Attributes** | SNMP Device | SNMP Enforcement Policies

Return Attributes | Request Attributes | Attribute Logging

Show policies that apply to: All roles

A RADIUS return attributes policy specifies the return list attributes to send to an 802.1X network access device, such as which VLAN endpoints must use to access the network. If no policy applies, Open Port is the default action.

		Policies	Attributes	Location Group	Interface	Applies to role
<input type="checkbox"/>	1.	Guest	Filter-Id=PERMIT-ALL in Termination-Action=1 Cisco- AVPair=subscriber.command=reauthenticate Cisco-AVPair=subscriber.reauthenticate- type=last	Guest Wired	N/A	Guest
<input type="checkbox"/>	2.	Guest Wired	Cisco-AVPair=url-redirect-acl=satha- redirect Cisco-AVPair=url- redirect=https://10.204.88.102/guest? ClientMacAddr=<callingStationId>	Guest Wired	N/A	Guest Wired Restricted

Keyboard shortcuts:
Use "<" and ">" keys to move selected items up and down (remember to click Save Changes after rearranging the list). Use Ctrl+Plus and Ctrl-Minus to expand and collapse all items.

11. The user configures the RADIUS URL-redirection attributes on the Cisco Switch. Using RADIUS URL-Redirection return attributes the Cisco switch redirects any initial HTTP/s traffic to IPS.

You must configure the following return attributes (supported only on Cisco switches):

```
Cisco-AVPAIR=url-redirect-acl=REDIRECT_To_IPS
Cisco-AVPAIR=url-redirect=https://<IPS-SIGN-IN-URL>/guest?ClientMacAddr=<callingStationId>
```

Here in redirect guest portal URL (* /guest), the "ClientMacAddr" is to identify the end client being redirected to IPS. As part of MAB authentication, IPS updates the value of radius return attribute "url-redirect" and replaces <callingStationId> with the client MAC address.

The RADIUS CoA configuration for various Cisco switch platforms is described below.

Cisco Platform	IOS Version	RADIUS CoA Configuration
3850	16.3	Filter-Id=PERMIT-ALL.in
2960X	15.2	Filter-Id=PERMIT-ALL.in
2960	12.2	Filter-Id=PERMIT-ALL.in CiscoAVPAIR=subscriber:command=reauthenticate Cisco-AVPAIR=subscriber:reauthenticate-type=last

Configuring IPS for Sponsored Guest Access

This section describes the configuration that is required for configuring Sponsored Guest access.

- Enable "Sponsored Guest Access" checkbox under Guest Authentication Server.
- Create a list of Sponsor's names in Guest Authentication Server.
- Create Role mapping rule in "Guest Admin" realm to point to "Sponsor" role for the list of sponsor's.
- If sponsor reside in AD, then AD needs to be selected as authentication server instead of "Guest Authentication" under "Guest Admin" realm.
- As part of default configuration, "sponsor" role is created with enabled sponsor management rights. This role can be used for sponsor approved guest access.

To configure IPS for Sponsored Guest access:

1. Select **Authentication > Auth. Servers**. The Authentication Servers screen appears. Click **Guest Authentication** available by default to view the settings.

The screenshot shows the 'Authentication Servers' interface. At the top, there's a 'New: (Select server type)' dropdown, 'New Server...' and 'Delete...' buttons. Below these are controls for '10 records per page' and a 'Search:' field. A table lists the authentication servers:

Authentication/Authorization Servers	Type
Administrators	Local Authentication
AD	Active Directory / Windows NT
Certificate Authentication	Certificate Server
Guest Authentication	Local Authentication
Guest Wired Authentication	MAC Address Authentication

The 'Guest Authentication' row is highlighted with a red box.

2. Select **Enable Sponsored Guest Access**.

Send guest user credentials via: ☐ SMS ☒ Email [Configure SMS/Email settings](#)

☒ Show credentials on screen after guest completes registration

☒ **Enable Sponsored Guest Access**

Response message for the Sponsor:

Localization

In a localized guest user environment when a user tries to register as a guest all the fields are displayed in that localized language, except the Company Name and Host or Sponsor fields which are displayed in English language.

French Language is used as an example.

To localize these two fields, an Admin user must enter the translated field names of Company Name and Host or Sponsor fields in the Guest Access Configurations section in IPS.

To make these changes:

Select **Authentication > Auth.Servers**. The Authentication Servers screen appears.

- Select a default Authentication Server to make the changes.
- The Settings tab of the Auth Server displays the settings.

Note: Use options on the Administrators/Users > Authentication > [Realm] > Authentication Policy > Password page to specify which realms should inherit the server's password management capabilities

Guest Access

Guest User Account Managers

☒ Enable Guest User Account Managers to administer Guest Accounts [Configure system GUAM settings](#)

Instructions for Guest User Account Manager:

☐ Maximum Account Validity Period: Set the Guest Account length limit (end time minus start time) in hours. This is valid for guests created by Guest Admin. Does not impact existing user expirations.

Guest Self-Registration

Send guest user credentials via: ☐ SMS ☒ Email [Configure SMS/Email settings](#)

☒ Show credentials on screen after guest completes registration

☐ Enable Sponsored Guest Access

☒ Maximum Account Validity Period for Self Registered Guests: Set the Guest Account length limit in hours. This is valid for self registered guests. Does not impact existing user expirations.

Note: To enable Guest Self-Registration navigate to Signing In > Sign-in Policies > User URLs > [url] > [Configure Guest Settings](#)

Common configuration for Guest User Account Managers and Guest Self-Registration

Guest User Name Prefix: Prefix applied to auto-generated user names.

Guest User Info Fields:

Enter additional fields for guest user information, one field per line. For example:
 Title
 Company name
 Sponsor

[Save Changes](#) [Reset](#)

- In the Guest Access Configurations section, enter the translated field names of Company Name and Host or Sponsor fields in the Guest User Info Fields box.
- Click **Save Changes** to save the settings.
- In the enterprise guest environment when a guest tries to register, the Company Name and Host or Sponsor fields are displayed in the respective language.

Nom complet *	<input type="text" value="Nom complet"/>
Adresse courriel	<input type="text" value="Adresse courriel"/>
Numéro de mobile	<div><div>Select ▼</div><div><input type="text" value="Numéro de mobile"/></div></div>
Nom de l'entreprise	<input type="text" value="Nom de l'entreprise"/>

<div><div>S'enregistrer</div><div>Annuler</div></div>	

Guest Self Registration

To enable Guest Self-Registration:

1. Select **Authentication > Signing In > Sign-in Policies > User URLs**.
2. Configure guest settings.

***/guest/**

User type: ☒ Users ☐ Administrators

Sign-in URL: Format: <host>:<path>/; Use * as wildcard in the beginning of the host name.

Description:

Sign-in page: To create or manage pages, see [Sign-In pages](#).

▼ **Authentication realm**

Specify what realms will be available when signing in.

	Available realms	Authentication protocol set	
	<input type="text" value="Cert Auth"/>	<input type="text" value="- Not applicable -"/>	<input type="button" value="Add"/>
	<input type="text" value="Guest"/>	<input type="text" value="Guest"/>	

If more than one realm appears above, Odyssey Access Client or the Policy Secure sign-in page will ask the user to choose. Other endpoints cannot choose a realm; the Policy Secure will assign the first suitable realm from the list. If no realms appear above, sign-in will fail.

☒ **User may specify the realm name as a Username suffix**
When this option is selected, the Username suffix will be used to specify a realm

☒ **Remove realm suffix before passing to authentication server**
When this option is selected, the username suffix will be stripped from the Username prior to authenticating with an authentication server

☒ **Fail if suffix does not match any of the realms**
When this option is selected, the user should provide one of the realm as suffix. If not, the user will be denied sign-in.

8. The Sponsor has the flexibility to edit the user details as shown in figure. For example, the Sponsorer can revoke the access by changing the setting to disabled.

The screenshot displays the 'Edit User' modal window. The 'Full Name' field contains 'M. Shankar'. The 'Email' field is partially visible. The 'Mobile Number' field has a dropdown menu set to 'Select'. The 'End Time' field shows '05/26/2017 8:32 PM'. The 'Company Name' field contains 'Juniper'. The 'Sponsor Name' field contains 'vshankar'. Below these fields are three checkboxes: 'Require user to change password at next sign in (Not applicable for Wireless LAN Controller deployment)', 'One-time use (disable account after the next successful sign-in)', and 'Enabled/Disabled'. The 'Disabled' option is selected and highlighted with a red box. At the bottom of the modal are 'Cancel' and 'Save Changes' buttons. The background interface shows a table of users with columns for Username, Status, and Actions. The table lists several users with IDs like guest_3200, guest_3202, guest_3199, guest_3201, guest_3203, guest_3197, and guest_3198. The status for the first three is 'Pending Approval' and for the others is 'Approved'. The 'Actions' column contains icons for edit, delete, and lock.

The following page is displayed if the Sponsor chooses to deny access to the Guest User. A notification email is sent to the Guest User describing that the access is denied.

Guest User Administration

Creating Guest User Accounts

When the guest user account manager (GUAM) logs in through the sign-in page for the guest realm, an interface is presented for creating accounts as shown in the following figure. The GUAM can view all the guest users created by the GUAM, self registered, and sponsor created users.

Settings	Guidelines
Username	Specify an account username. If the local authentication server has been configured with a prefix for guest accounts, the username box is populated with the next username in the prefix-based sequence. We recommend you retain the guest_ prefix so that you can rely on the naming convention in your role mapping rules.
Full Name	Specify the name of the guest.
Password	A strong password is generated automatically, or you can specify a different password. After you have saved the configuration, the system displays the password characters as asterisks (*) instead of blanks or cleartext.

Settings	Guidelines
	 The password cannot be decrypted later unless the appropriate option is set when you create a local authentication server.
Mobile Number	Select the country name and then specify a valid phone number of the guest user. The IPS sends the login credentials to this mobile number through SMS.
Email	Specify an email address you can use to contact the guest if necessary.
Start Time	By default, the 'Now' option is displayed. You can specify a start time for the account activity period by clicking on the drop-down and selecting from the calendar menu.
End Time	<p>By default, 'After 24 hours' is displayed. You can specify an end of the account activity period. Click on the drop-down menu and select from the calendar menu. Once a user account has expired, it is deleted from the system.</p> <p>The process that deletes the guest user account runs every ten minutes. There may be a delay of some minutes before the account is purged. Even if the time or date on the system is moved ahead past the expiration time, the account could still be valid until the purge process runs. One-time user accounts are not affected by the ten-minute delay: one-time accounts are deleted immediately after the user exits.</p>
Company Name	Enter the name of the company of the guest.
Host or Sponsor	Enter whether the guest is a Host or Sponsor.
One-time use	Select this option if you want the account deleted immediately after the guest user exits the browser or signs out.
Enabled	Select this option to enable the account
Require user to change password at next sign in	<p>Select this option to prompt the user to change the configured password.</p>  This option will not be supported in GUAM for WLC case. This option should not be enabled. Even if enabled, it will not have any effect.

The following figure shows the page for adding many users and table describes the user configuration.

There may be a delay of some minutes before the account is purged. Even if the time or date on the system is moved ahead past the expiration time, the account could still be valid until the purge process runs. One-time user accounts are not affected by the ten-minute delay: one-time accounts are deleted immediately after the user exits.</p>
Company Name	Enter the name of the company of the guest. (Optional)
Host or Sponsor	Enter whether the guest is a Host or Sponsor. (Optional)
One-time use	Select this option if you want the account deleted immediately after the guest user exits the browser or signs out
Enabled	Select this option to enable the account.
Require user to change password at next sign in	<p>Select this option to prompt the user to change the configured password</p> <hr/> <p> This option will not be supported in GUAM for WLC case. This option should not be enabled. Even if enabled, it will not have any effect.</p> <hr/>

After the GUAM user clicks the Create button the following popup is displayed.

Approve Guest User(s)

Would you like to approve guest user(s) bhishek@gmail.com?

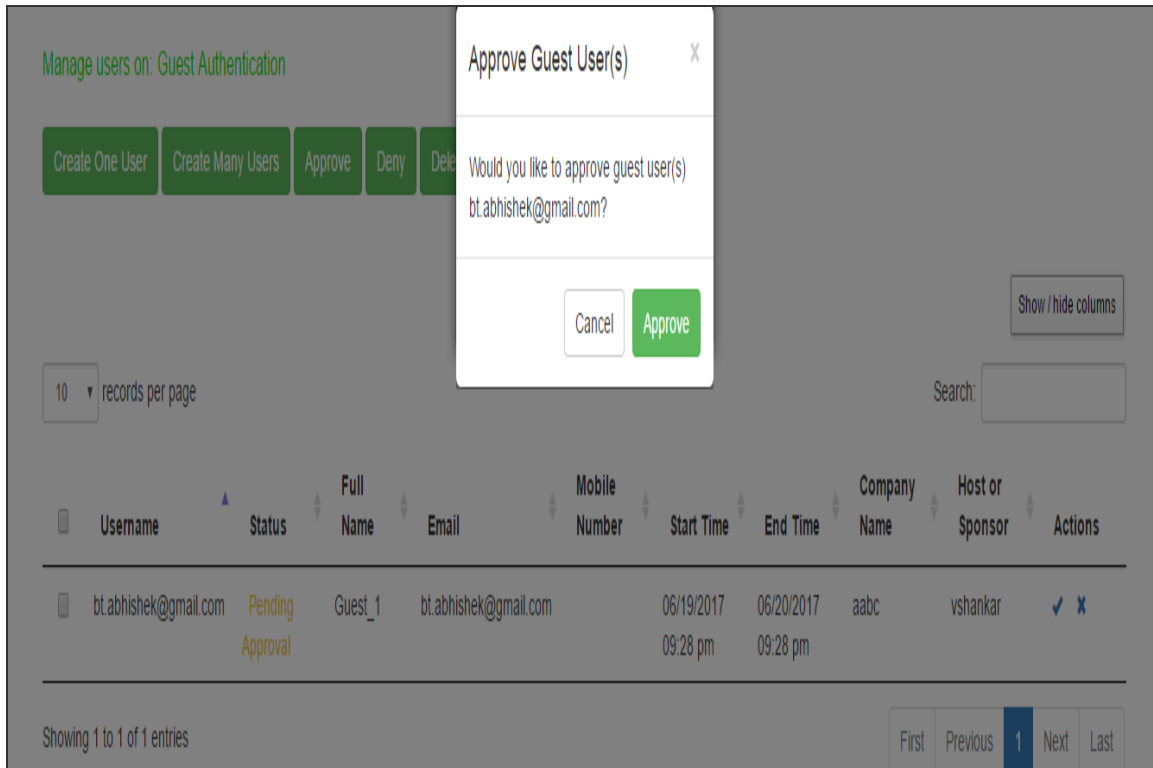

Cancel Approve

1. Click Approve. The Guest User receives a notification email describing that the access is approved.

The Sponsor has the flexibility to edit the user details as shown below.

The following page is displayed if the Sponsor chooses to deny access to the Guest User. A notification email is sent to the Guest User describing that the access is denied.

Customizing Guest Self Registration User Pages

The customization for GUAM is no more supported from the IPS 5.2 release.

This topic describes how to customize the Guest Self Register page. It includes the following information:

- Downloading the Sample Template Files
- Modifying the Sample Template Files
- Uploading Your Customized Files
- Using the Customized Pages
- Verifying the Customization

Downloading the Sample Template Files

The sample template zip file includes the following files which are added for the IPS 5.2 release:

- GuestLoginPage.thtml
- GuestLogout.thtml
- GuestSelfRegistration.thtml
- GuestForgotPassword.thtml
- GuestSigninNotifPreAuth.thtml

To download the sample template files:

1. Select **Authentication > Signing In > Sign in** pages. The Signing In screen appears.
2. Click **Upload Custom** Pages.
3. The **Upload Custom Sign-In Pages** screen appears. This page hosts the sample.zip files which can be used to customize the guest sign in pages.
4. Click the Sample link in the Sample Template Files pane.
5. Download the latest sample.zip file.

Modifying the Sample Template Files

You can edit the HTML to modify the look and feel of your page. You can add, modify, or delete JavaScript functions and variables to customize the functionality presented on your page. This section provides examples of common customizations for Guest Self Registration pages. For a reference on the files, functions, and variables found in the templates included in the sample.zip file, see the Custom Sign-In Pages Developer Reference.

Figure shows the contents of the GuestSelfRegistration.thtml file. The JavaScript functions and variables used for the standard user interface controls that appear in the predefined pages are highlighted in bold.

Table describes some of the common variables used in the templates and their meaning.

Variable	Definition
I18N_FULL_NAME	Field for entering the full name of guest user.
I18N_USERNAME_ADMIN_EMAIL	Field for entering the email id of guest user.

Variable	Definition
I18N_USER_ADMIN_MOBILE_NUMBER	Field for entering mobile number of guest user.
I18N_USER_ADMIN_REGISTER	Register option in the Guest Self Registration page. Click the button after entering the user details.
I18N_CANCEL	Cancel option. Cancels the registration process and takes the user back to the Sign In page of Guest User
I18N_USERNAME_COLON	Username: field. It displays the username in the confirmation box.
I18N_PASSWORD_COLON	Password: field. It displays the password in the confirmation box.
I18N_USER_ADMIN_CREATING_ACCOUNT	Displays the message "An account has been created for you" in the confirmation box.

```

<div id= "fnDiv" class="form-group required">
  <label for="fullname" class="col-sm-2 control-label"><% I18N_
FULL_NAME %></label>
  <div id="fnDiv2" class="col-sm-5">
    <input type="text" class="form-control" id="fullname"
name="fullname" placeholder="<% I18N_FULL_NAME %>" autofocus
validate>
  </div>
</div>

<div id= "emailDiv" class="form-group <%IF emailRequired == 1%>
required <%END%>">
  <label for="email" class="col-sm-2 control-label"><% I18N_USER_
ADMIN_EMAIL %></label>
  <div id="emailDiv2" class="col-sm-5">
    <input type="email" class="form-control" id="email"
name="email" placeholder="<% I18N_USER_ADMIN_EMAIL %>" validate>
  </div>
</div>

<div id= "mnDiv" class="form-group <%IF smsRequired == 1%> required
<%END%>">
  <label for="mobilenumber" class="col-sm-2 control-label"><% I18N_
USER_ADMIN_MOBILE_NUMBER %></label>
  <div id="mnDiv1" class="col-sm-2">

```

```

        <select id="cmbCountryCode" class="form-control"
name="cmbCountryCode" <%disabled%>>
        <% FOREACH country = countryCode %>
            <option id="<% country.id %>" value="<% country.id %>"
<%IF countrySelected == country.id%> selected <%END%>> <%
country.name %> </option>
        <%END%>
    </select>
</div>
<div id="mnDiv2" class="col-sm-3">
    <input type="tel" class="form-control" id="mobilenumber"
name="mobilenumber" placeholder="<% I18N_USER_ADMIN_MOBILE_NUMBER %>"
validate>
</div>
</div>

```

Removing Fields

You can remove fields from the user interface form by deleting the HTML and JavaScript that define them from the sample file. For example, to delete the “Email” option box, delete the following HTML and variables:

Example

```

<div id= "emailDiv" class="form-group <%IF emailRequired == 1%>
required <%END%>">
    <label for="email" class="col-sm-2 control-label"><% I18N_USER_
ADMIN_EMAIL %></label>
    <div id="emailDiv2" class="col-sm-5">
        <input type="email" class="form-control" id="email"
name="email" placeholder="<% I18N_USER_ADMIN_EMAIL %>" validate>
    </div>
</div>

```

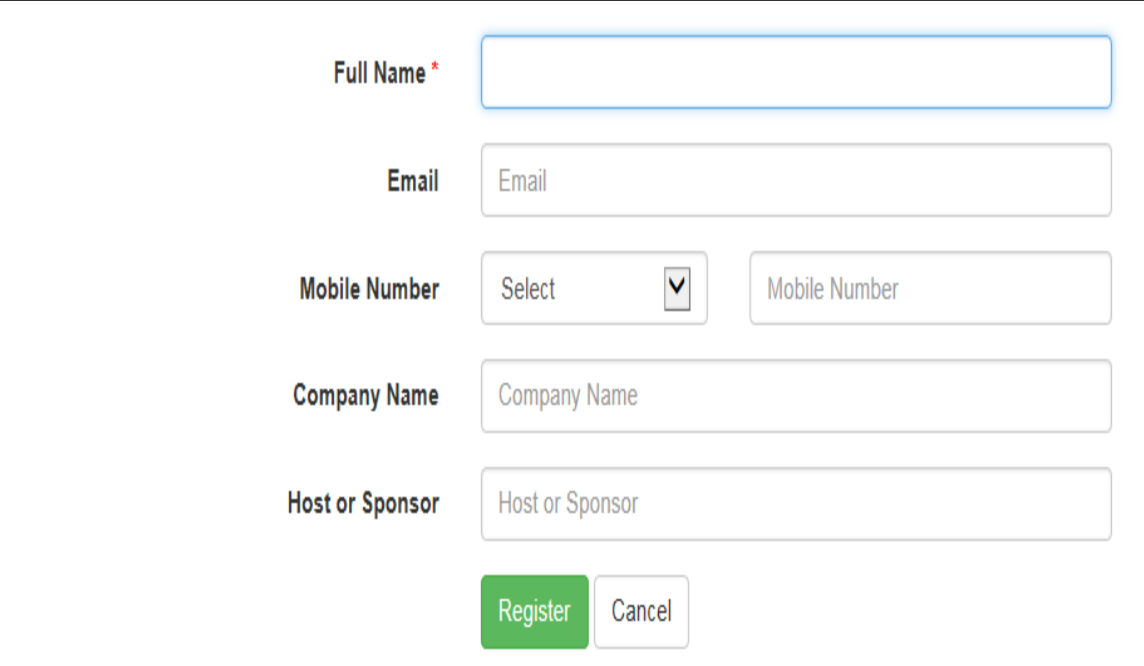

Never delete or modify the following required variables:

```

Guest_Includes-
signinAgainUrl-
LoginPageErrorMessage-Specifies the error message. The device
generates the error message in case of an error otherwise it will be
empty

```

```
preAuthSNTxt
```

Editing Fields

You can edit fields in the user interface form by editing the HTML and JavaScript that define them from the sample file. For example, to edit the "Mobile Number" option box as 'Contact Number', edit the following HTML and variables:

Script Before Editing

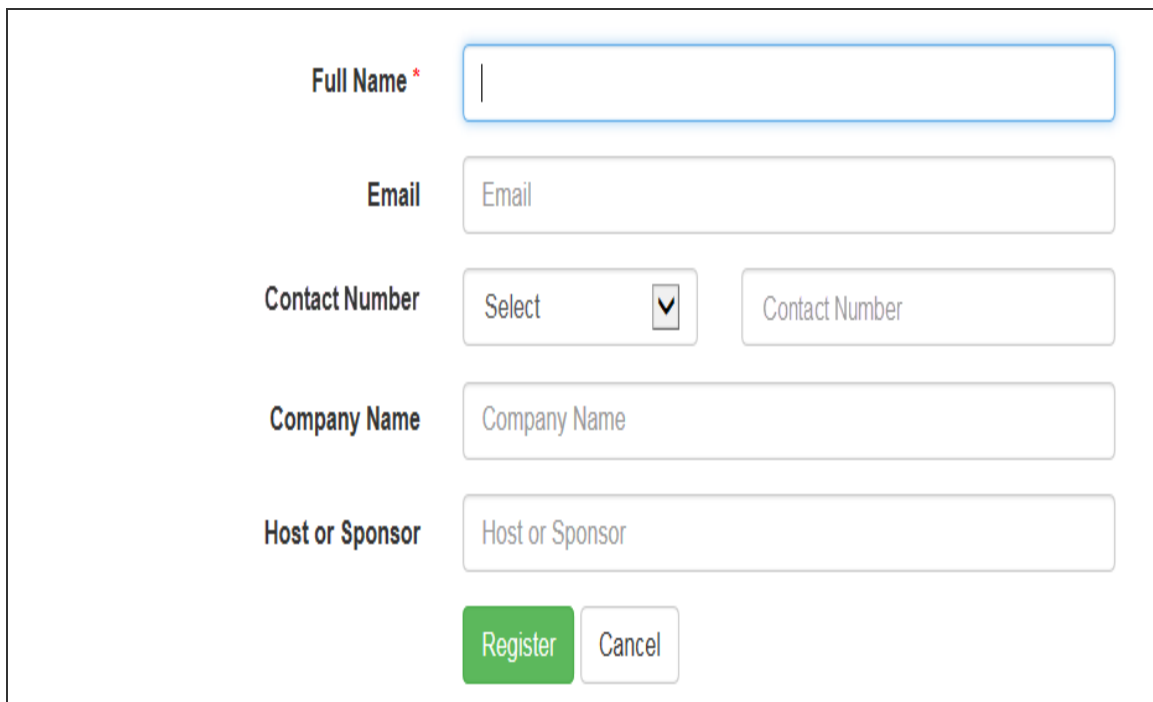

```
<div id= "mnDiv" class="form-group <%IF smsRequired == 1%> required
<%END%>">
    <label for="mobilenumber" class="col-sm-2 control-label"> <%
I18N_USER_ADMIN_MOBILE_NUMBER %>Contact Number</label>
    <div id="mnDiv1" class="col-sm-2">
        <select id="cmbCountryCode" class="form-control"
name="cmbCountryCode" <%disabled%>>
            <% FOREACH country = countryCode %>
                <option id="<% country.id %>" value="<% country.id %>"
<%IF countrySelected == country.id%> selected <%END%>> <%
country.name %> </option>
            <%END%>
        </select>
    </div>
    <div id="mnDiv2" class="col-sm-3">
        <input type="tel" class="form-control" id="mobilenumber"
name="mobilenumber" placeholder="<% I18N_USER_ADMIN_MOBILE_NUMBER %>"
validate>
    </div>
</div>
```

Script After Editing

```
<div id= "mnDiv" class="form-group <%IF smsRequired == 1%> required
<%END%>">
    <label for="mobilenumber" class="col-sm-2 control-label"> Contact
Number</label>
    <div id="mnDiv1" class="col-sm-2">
        <select id="cmbCountryCode" class="form-control"
name="cmbCountryCode" <%disabled%>>
            <% FOREACH country = countryCode %>
```

```
        <option id="<% country.id %>" value="<% country.id %>"
<%IF countrySelected == country.id%> selected <%END%>> <%
country.name %> </option>
        <%END%>
    </select>
</div>
<div id="mnDiv2" class="col-sm-3">
    <input type="tel" class="form-control" id="mobilenumber"
name="mobilenumber" placeholder="Contact Number" validate>
</div>
</div>
```

Figure shows the result of the customization

The image shows a registration form with the following fields and controls:

- Full Name ***: A text input field with a blue border and a cursor.
- Email**: A text input field with the placeholder text "Email".
- Contact Number**: A dropdown menu with "Select" and a downward arrow, followed by a text input field with the placeholder text "Contact Number".
- Company Name**: A text input field with the placeholder text "Company Name".
- Host or Sponsor**: A text input field with the placeholder text "Host or Sponsor".
- Buttons**: A green "Register" button and a white "Cancel" button.

Uploading Your Customized Files

After you have edited the sample template files, save the files with the same name and add them to the sample.zip file (replacing the previous files).

To upload the files to the system:

1. Select **Signing In > Sign-in pages**.
2. Click **Browse** to select the sample.zip file containing the custom templates and assets.
3. Click **Upload Custom Pages**.
4. The Upload Custom Sign-In Pages screen appears.

Setting	Guidelines
Sign-In Pages	
Name	Specify the name for the sign-in page.
Page Type	Specify the page type. Access is selected by default.
Template File	Select the template file in zipped format that contains the custom templates and assets.
Upload	
Skip validation checks during upload	Select this option to skip the validation checks for the template file.
Upload Custom Pages	Select this option to upload the custom pages.

Using the Customized Pages

After you have uploaded the customized files, you can associate them with your Guest Self Registration sign-in page.

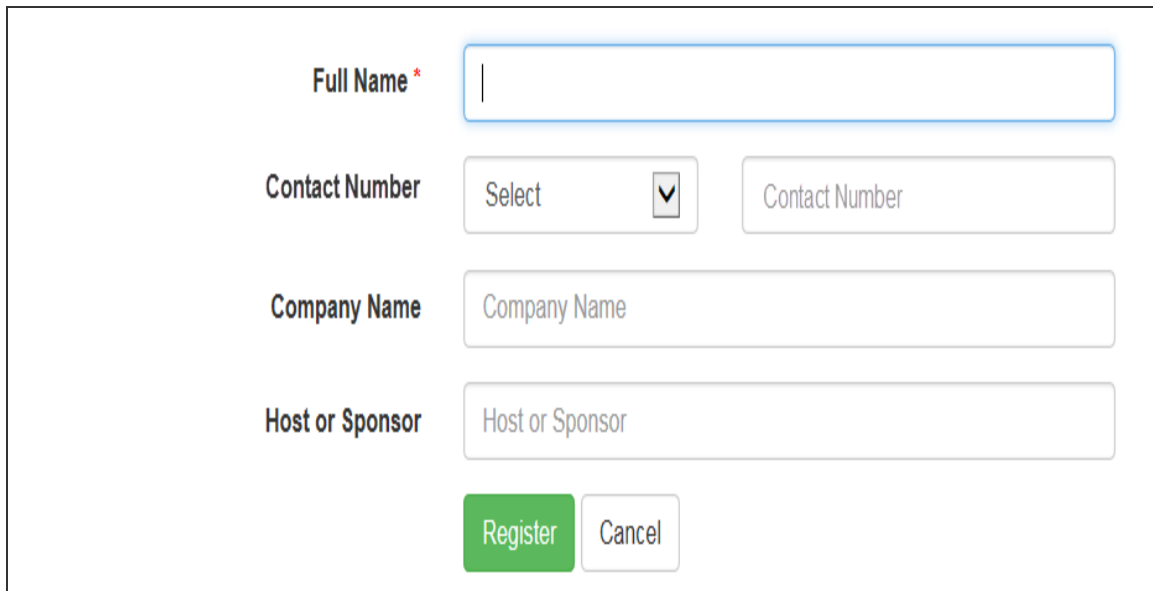

To use the customized pages:

1. Select **Authentication > Signing-In > Sign-In Policies** to display the sign-in policies configuration page.
2. Select the custom sign-in page from the drop-down list..
3. Click **Save Changes**.

Verifying the Customization

Sign in to the Guest Self Registration sign-in page as a guest user account manager and verify that the customizations you have made were applied.

Figure shows the customized Guest Self Registration page, without the Email ID field, and the Mobile Number field changed as Contact Number.

The screenshot displays a registration form with the following fields and controls:

- Full Name ***: A text input field with a blue border and a vertical cursor.
- Contact Number**: A dropdown menu showing "Select" with a downward arrow, followed by a text input field containing the placeholder "Contact Number".
- Company Name**: A text input field with the placeholder "Company Name".
- Host or Sponsor**: A text input field with the placeholder "Host or Sponsor".
- Buttons**: A green "Register" button and a white "Cancel" button with a grey border.

Configuring Cisco 2500 WLC

Configuring Cisco WLC for IPS GUAM and Guest Self-Registration

This section explains the steps to configure Cisco 2500 WLC for deploying IPS GUAM and Guest Self-Registration feature. This section provides examples of how to configure the Cisco WLC. For more information, see Cisco documentation.

Configuration Required on Cisco WLC for Local AP mode

Configuring RADIUS server

1. Login to Cisco WLC. Select **Security > AAA > RADIUS**. Configure IPS server as authentication and accounting servers.

2. Support for RFC 3576 - Enable this option to trigger RADIUS disconnect when required.

Auth Servers > Guest Authentication

Guest Authentication

Settings Users Admin Users

*Name: Label to reference this server.

✓ Password Options

Minimum length: characters

Maximum length: characters

☐ Password must have at least digits

☐ Password must have at least letters

☐ Password must have mix of UPPERCASE and lowercase letters

☒ Password must be different from username

☒ New passwords must be different from previous password

☐ Password stored as clear text This option can only be set during create.

Note: If password stored as clear text, more authentication protocols, i.e. CHAP, EAP-MD5, are supported

✓ Password Management

☒ Allow users to change their passwords

☐ Force password change after days

☐ Prompt users to change their password days before current password expires

Note: Use options on the Administrators/Users > Authentication > [Realm] > Authentication Policy > Password page to specify which realms should inherit the server's password management capabilities

✓ Guest Access

Guest User Account Managers

☒ Enable Guest User Account Managers to administer Guest Accounts Configure system GUAM settings

Instructions displayed for guest users creation and updation. You can use
,
, <div>, <div>, <noscript>, and tags to format the text.

Instructions for Guest User Account Manager:

☐ Maximum Account Validity Period: Set the Guest Account length limit (end time minus start time) in hours. This is valid for guests created by Guest Admin. Does not impact existing user expirations.

Guest Self-Registration

Send guest user credentials via: ☐ SMS ☒ Email Configure SMS/Email settings

☒ Show credentials on screen after guest completes registration

☒ Enable Sponsored Guest Access

Response message for the Sponsor: This message will be sent as email to the sponsor.

Approve message for the Guest: This message will be sent as email/SMS to the guest user.

Deny message for the Guest: This message will be sent as email/SMS to the guest user.

☒ Maximum Account Validity Period for Self Registered Guests: Set the Guest Account length limit in hours. This is valid for self registered guests. Does not impact existing user expirations.

Note: To enable Guest Self-Registration navigate to Signing In > Sign-in Policies > User URLs > [url] > Configure Guest Settings

Common configuration for Guest User Account Managers and Guest Self-Registration

Guest User Name Prefix: Prefix applied to auto-generated user names.

Guest User Info Fields:

Field Name	Field Type
Company Name	Text
Host or Sponsor	Text

Enter additional fields for guest user information, one field per line. For example:
Title
Company name
Sponsor

* Indicates required field

The screenshot shows the Cisco WLC configuration interface. The top navigation bar includes links for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY (highlighted), MANAGEMENT, COMMANDS, HELP, and FEEDBACK. The left sidebar shows the Security menu with options like AAA, RADIUS, TACACS+, LDAP, Local EAP, Priority Order, Certificate, Access Control Lists, and Wireless Protection. The main content area is titled 'RADIUS Authentication Servers > New' and contains the following configuration fields:

Server Index (Priority)	3 ▼
Server IP Address	3.3.3.2
Shared Secret Format	ASCII ▼
Shared Secret	*****
Confirm Shared Secret	*****
Key Wrap	<input type="checkbox"/> (Designed for FIPS customers and requires a key wrap compliant RADIUS server)
Port Number	1812
Server Status	Enabled ▼
Support for RFC 3576	Enabled ▼
Server Timeout	2 seconds
Network User	<input checked="" type="checkbox"/> Enable
Management	<input checked="" type="checkbox"/> Enable
IPSec	<input type="checkbox"/> Enable

Using CLI

Before creating the radius server, you need to allot an index number to it which is not currently in use. To find out the index numbers which are currently in use in WLC, use the following command:

```
show radius summary
```

Go through the authentication servers and accounting servers section in the displayed output. Use an unused index number for adding radius authentication or accounting server.

```
config radius auth add <RADIUS auth server ID> <RADIUS server IP>
1812 ascii <password>
config radius auth disable < RADIUS auth server ID >
config radius auth rfc3576 enable < RADIUS auth server ID >
config radius auth enable < RADIUS auth server ID >
config radius acct add <RADIUS acct server ID > <RADIUS server IP>
1813 ascii <password>
```

Configuring ACLs

1. On the CISCO WLC main screen go to **Security > Access Control Lists**. Create an IPv4 ACL list to allow DNS, DHCP and IPS (Traffic).

Access Control Lists > Edit

General

Access List Name: test

Deny Counters: 0

Seq	Action	Source IP/Mask	Destination IP/Mask	Protocol	Source Port	Dest Port	DSCP	Direction	Number of Hits
1	Permit	0.0.0.0 / 0.0.0.0	0.0.0.0 / 0.0.0.0	UDP	DHCP Client	Any	Any	Any	0
2	Permit	0.0.0.0 / 0.0.0.0	0.0.0.0 / 0.0.0.0	UDP	DHCP Server	Any	Any	Any	0
3	Permit	0.0.0.0 / 0.0.0.0	0.0.0.0 / 0.0.0.0	UDP	DNS	Any	Any	Any	0
4	Permit	0.0.0.0 / 0.0.0.0	0.0.0.0 / 0.0.0.0	UDP	Any	DNS	Any	Any	0
5	Permit	3.3.3.0 / 255.255.255.0	3.3.3.0 / 255.255.255.0	Any	Any	Any	Any	Any	0
6	Permit	0.0.0.0 / 0.0.0.0	0.0.0.0 / 0.0.0.0	Any	Any	Any	Any	Any	0

Using CLI

To see all the ACLs that are configured on the controller enter the following command:

```
show acl summary
```

To create an ACL with name test

```
config acl create test
```

To create a rule in the test ACL

```
config acl rule add test 1 # Creating Rule No 1
```

```
config acl rule protocol test 1 17 # 17 is UDP protocol
```

```
config acl rule source port range test 1 68 68 # 68 is DHCP client port number
```

```
config acl rule action test 1 permit # Allow access

config acl rule add test 2 # Creating Rule No 2
config acl rule protocol test 2 17
config acl rule source port range test 2 67 67 # 67 is DHCP server
port number
config acl rule action test 2 permit

config acl rule add test 3 # Creating Rule No 3
config acl rule protocol test 3 17
config acl rule source port range test 3 53 53 # Port 53 for DNS
config acl rule action test 3 permit

config acl rule add test 4 # Creating Rule No 4
config acl rule protocol test 4 17
config acl rule destination port range test 4 53 53
config acl rule action test 4 permit

config acl rule add test 5 # Creating Rule No 5
config acl rule source address test 5 3.3.3.2 255.255.255.255
config acl rule action test 5 permit

config acl rule add test 6 # Creating Rule No 6
config acl rule destination address test 6 3.3.3.2 255.255.255.255
config acl rule action test 6 permit
```

Configuring WLAN

To configure Cisco WLAN:

1. On the CISCO WLC main screen select WLANs tab and create a new WLAN.

The screenshot shows the Cisco WLC main screen with the 'WLANs' tab selected. The 'WLANs > New' configuration page is displayed. The left sidebar shows 'WLANs' and 'Advanced' options. The main content area has the following fields:

Field	Value
Type	WLAN
Profile Name	Test
SSID	test
ID	10

2. Select to General tab and enable Status checkbox

The screenshot shows the Cisco WLC main screen with the 'WLANs' tab selected. The 'WLANs > Edit' configuration page for the 'Test' WLAN is displayed. The left sidebar shows 'WLANs' and 'Advanced' options. The main content area has the following tabs: General, Security, QoS, Policy-Mapping, and Advanced. The 'General' tab is selected, and the 'AAA Servers' sub-tab is active. The 'AAA Servers' section includes the following fields:

Field	Value
Radius Server Overwrite interface	<input type="checkbox"/> Enabled
Authentication Servers	<input checked="" type="checkbox"/> Enabled
Accounting Servers	<input checked="" type="checkbox"/> Enabled
Server 1	IP:3.3.3.2, Port:1812
Server 2	None
Server 3	None
Server 4	None
Server 5	None
Server 6	None
Radius Server Accounting	<input checked="" type="checkbox"/> Interim Interval 600

3. Select Security > Layer 2 in WLANs tab. Select 'None' from the Layer 2 Security drop-down list.

The screenshot displays the Cisco WLAN configuration interface. The top navigation bar includes the Cisco logo and tabs for MONITOR, WLANs (selected), CONTROLLER, WIRELESS, SECURITY, and MANAGEMENT. On the left, the WLANs sidebar shows 'WLANs' and 'Advanced' options. The main content area is titled 'WLANs > Edit 'Test''. It features a tabbed interface with 'General', 'Security', 'QoS', 'Policy-Mapping', and 'Advanced'. The 'Security' tab is active, and within it, the 'Layer 2' sub-tab is selected. The 'Layer 2 Security' dropdown menu is set to 'None'. Below this, the 'MAC Filtering' checkbox is unchecked. The 'Fast Transition' section also has an unchecked checkbox.

WLANs

WLANs > Edit 'Test'

General Security QoS Policy-Mapping Advanced

Layer 2 Layer 3 AAA Servers

Layer 2 Security [6](#) None

MAC Filtering [9](#) ☐

Fast Transition

Fast Transition ☐

4. Select **Security > Layer3 in WLANs** tab.

- From the Layer 3 security drop-down list select 'Web Policy'.
- For Preauthentication ACL, associate the ACL that is created earlier for IPv4.
- Over-ride Global Config - Select the Enable check box.
- From the Web auth type drop-down list select External (Re-direct to external server)
- URL – Enter the IPS (Guest sign-in URL) for redirection URL.

The screenshot shows the Cisco WLAN configuration interface. The top navigation bar includes links for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, COMMANDS, HELP, and FEEDBACK. The left sidebar shows the WLAN configuration tree with 'WLANs' and 'Advanced' options. The main content area is titled 'WLANs > Edit 'Test'' and features several tabs: General, Security, QoS, Policy-Mapping, and Advanced. Under the Security tab, there are sub-tabs for Layer 2, Layer 3, and AAA Servers. The Layer 3 tab is active, showing the 'Layer 3 Security' dropdown set to 'Web Policy'. Below this, there are radio buttons for Authentication (selected), Passthrough, Conditional Web Redirect, Splash Page Web Redirect, and On MAC Filter failure. The Preauthentication ACL section shows IPv4 set to 'Test', IPv6 set to 'None', and WebAuth FlexAcl set to 'None'. The Sleeping Client checkbox is unchecked. The Over-ride Global Config checkbox is checked (labeled 'Enable'). The Web Auth type dropdown is set to 'External(Re-direct to external server)'. The URL field contains 'https://3.3.2/guest'.

5. Select **Security** > **AAA Servers** tab. Configure RADIUS server for authentication and accounting.

The screenshot shows the Cisco WLAN configuration interface. The left sidebar has a 'WLANs' section with 'WLANs' and 'Advanced' options. The main content area is titled 'WLANs > Edit 'Test''. It features a top navigation bar with tabs: 'General', 'Security', 'QoS', 'Policy-Mapping', and 'Advanced'. Below this, there are sub-tabs: 'Layer 2', 'Layer 3', and 'AAA Servers'. The 'AAA Servers' tab is active. It contains a section 'Select AAA servers below to override use of default servers on this WLAN'. Under 'Radius Servers', there is a checkbox for 'Radius Server Overwrite interface' which is not checked. Below this, there are two columns: 'Authentication Servers' and 'Accounting Servers'. Each column has a table with 6 rows (Server 1 to Server 6). The 'Authentication Servers' column has a checkbox for 'Enabled' which is checked, and a dropdown menu showing 'IP:3.3.3.2, Port:1812'. The 'Accounting Servers' column has a checkbox for 'Enabled' which is checked, and a dropdown menu showing 'IP:3.3.3.2, Port:1813'. At the bottom, there is a section 'Radius Server Accounting' with a checkbox for 'Interim Update' which is checked, and a text input for 'Interim Interval' with the value '600'.

WLANs > Edit 'Test'

General Security QoS Policy-Mapping Advanced

Layer 2 Layer 3 AAA Servers

Select AAA servers below to override use of default servers on this WLAN

Radius Servers

Radius Server Overwrite interface ☐ Enabled

Authentication Servers Accounting Servers

Server	Authentication Servers	Accounting Servers
Server 1	<input checked="" type="checkbox"/> Enabled IP:3.3.3.2, Port:1812	<input checked="" type="checkbox"/> Enabled IP:3.3.3.2, Port:1813
Server 2	None	None
Server 3	None	None
Server 4	None	None
Server 5	None	None
Server 6	None	None

Radius Server Accounting

Interim Update ☒ Interim Interval 600

6. Select the **Interim Update** check box.

Instead of management port, if some other Interface/Interface Group (G) is selected during WLAN creation then Radius Server Overwrite interface option must be enabled.

The screenshot shows the Cisco WLAN configuration interface for a WLAN named 'Test'. The 'AAA Servers' tab is selected, and the 'Radius Servers' section is visible. The 'Radius Server Overwrite interface' checkbox is checked and highlighted with a red arrow. The 'Interface Priority' is set to 'WLAN'. Below this, there are sections for 'Authentication Servers' and 'Accounting Servers'.

Server	Enabled	IP:Port	Enabled	IP:Port
Server 1	<input checked="" type="checkbox"/>	IP:3.3.3.2, Port:1812	<input checked="" type="checkbox"/>	IP:3.3.3.2, Port:1813
Server 2	<input type="checkbox"/>	None	<input type="checkbox"/>	None
Server 3	<input type="checkbox"/>	None	<input type="checkbox"/>	None
Server 4	<input type="checkbox"/>	None	<input type="checkbox"/>	None
Server 5	<input type="checkbox"/>	None	<input type="checkbox"/>	None
Server 6	<input type="checkbox"/>	None	<input type="checkbox"/>	None

7. Select **Advanced** tab and enable Allow AAA Override checkbox.

The screenshot shows the Cisco WLAN configuration interface for a WLAN named 'test'. The 'Advanced' tab is selected. The 'Allow AAA Override' checkbox is checked. Other settings include 'Coverage Hole Detection' (checked), 'Enable Session Timeout' (unchecked), 'Aironet IE' (checked), 'Diagnostic Channel' (unchecked), and 'Override Interface ACL' (IPv4: None, IPv6: None).

Setting	Value
Allow AAA Override	<input checked="" type="checkbox"/> Enabled
Coverage Hole Detection	<input checked="" type="checkbox"/> Enabled
Enable Session Timeout	<input type="checkbox"/> Disabled
Aironet IE	<input checked="" type="checkbox"/> Enabled
Diagnostic Channel	<input type="checkbox"/> Disabled
Override Interface ACL	IPv4: None, IPv6: None

Using CLI

Before creating a new WLAN verify the existing WLANs on the WLC using the following command and use an unused index id for the new WLAN.

```
show wlan summary
To create a new WLAN
config wlan create <WLAN_ID> <Profile name> <SSID>
Ex: - config wlan create 10 Test Test      # Test is the WLAN name and
SSID
config wlan interface <WLAN_ID> <interface-name>
Ex: - config wlan interface 10 management # assigning the WLAN to
management port
config wlan security wpa disable <WLAN_ID>
config wlan security web-auth enable <WLAN_ID>
config wlan custom-web global disable <WLAN_ID>
config wlan custom-web ext-webauth-url <ext-webauth-url> <WLAN_ID>
config wlan custom-web webauth-type external <WLAN_ID>
config wlan security web-auth acl <WLAN_ID> <ACL_name>
config wlan radius_server auth add <WLAN_ID> <Radius_auth_server_ID>
config wlan radius_server acct add <WLAN_ID> <Radius_acct_server_ID>
config wlan radius_server overwrite-interface enable <WLAN_ID> (
This command is required only if instead of management, some other
interface is configured for WLAN. Please
check steps 2 and 5)
config wlan radius_server acct interim-update enable <WLAN_ID>
config wlan radius_server acct interim-update <Interval> <WLAN_ID>
config wlan aaa-override enable <WLAN_ID>
config wlan enable <WLAN_ID>
Configuring AP Group
On the CISCO WLC main screen go to WLANs > Advanced > AP Groups
screen and map WLAN to the Local AP (Campus Only mode) group.
```

WLANs

▼ WLANs
WLANs

▼ Advanced
AP Groups

Ap Groups > Edit 'lwsgrp'

General WLANs RF Profile APs 802.11u

Add New

WLAN ID	WLAN SSID ²	Interface/Interface Group(G)	SNMP NAC State
1	LWS	vlan255	Disabled
2	lwsdot1x	vlan74	Disabled
5	lwsnew	vlan255	Disabled
6	cisco-8021x	vlan74	Disabled
7	test	management	Disabled

Using the CLI

```
config wlan apgroup interface-mapping add <APgroup Name> <WLAN ID>
<interfacename>
```

To save the configuration use the following command:

```
save config
```

Configuration Required on Cisco WLC for Remote AP mode

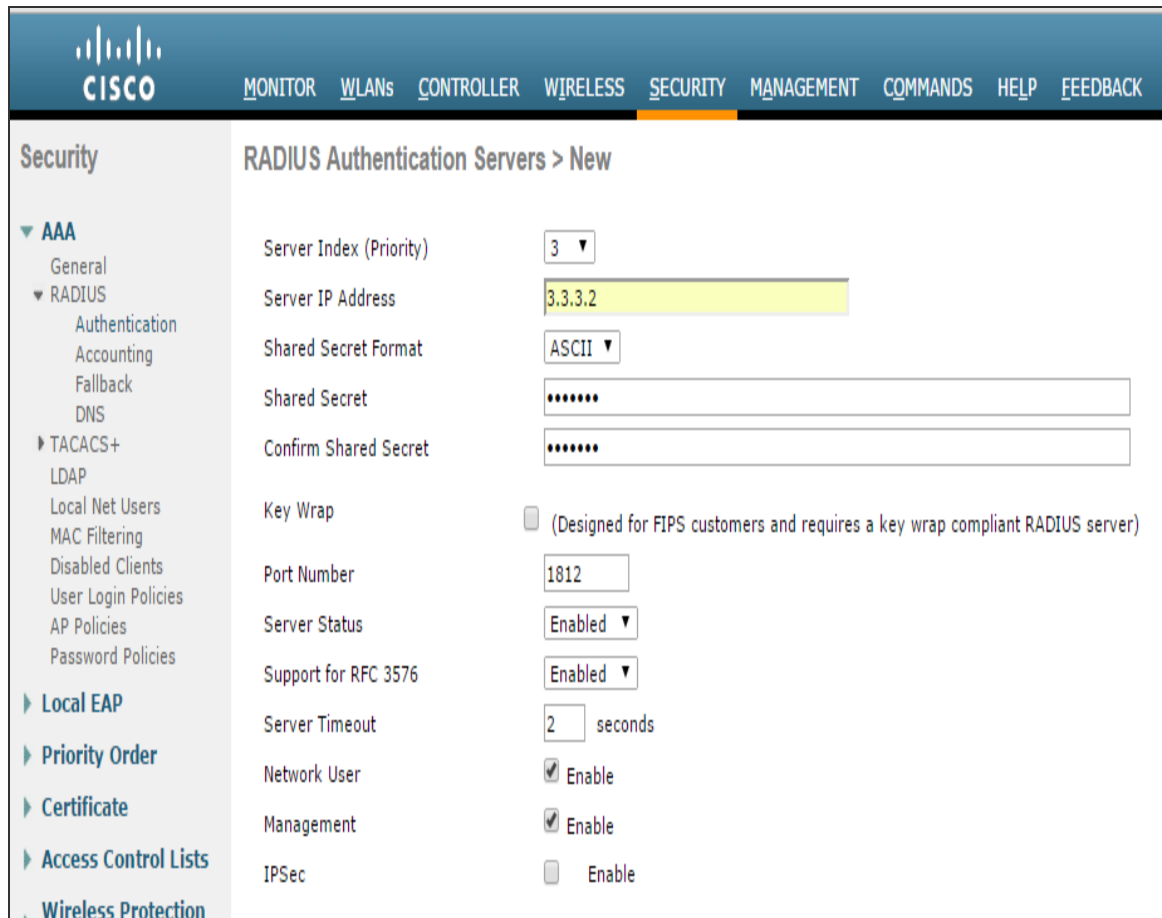

Configuring RADIUS server

1. Login to Cisco WLC. Go to **Security > AAA > RADIUS**. Configure IPS server as authentication and accounting server.

2. **Support for RFC 3576** - Enable this option to trigger RADIUS disconnect when required.

Support for RFC3576 for RADIUS disconnect does not work properly with Cisco 2500, 5500, 7500, and 8500 series.

The image shows the Cisco Security Configuration Interface for adding a new RADIUS Authentication Server. The interface has a top navigation bar with tabs: MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY (selected), MANAGEMENT, COMMANDS, HELP, and FEEDBACK. On the left, a 'Security' sidebar lists various configuration areas, with 'AAA' expanded to show 'RADIUS'. The main area is titled 'RADIUS Authentication Servers > New' and contains the following configuration fields:

Field	Value
Server Index (Priority)	3
Server IP Address	3.3.3.2
Shared Secret Format	ASCII
Shared Secret	*****
Confirm Shared Secret	*****
Key Wrap	<input type="checkbox"/> (Designed for FIPS customers and requires a key wrap compliant RADIUS server)
Port Number	1812
Server Status	Enabled
Support for RFC 3576	Enabled
Server Timeout	2 seconds
Network User	<input checked="" type="checkbox"/> Enable
Management	<input checked="" type="checkbox"/> Enable
IPSec	<input type="checkbox"/> Enable

The screenshot shows the Cisco WLC configuration interface. The top navigation bar includes links for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY (highlighted), MANAGEMENT, COMMANDS, HELP, and FEEDBACK. The left sidebar shows the 'Security' section expanded, with 'AAA' and 'RADIUS' sub-sections. The main content area is titled 'RADIUS Accounting Servers > New'. It contains the following configuration fields:

Server Index (Priority)	7 ▼
Server IP Address	3.3.3.2
Shared Secret Format	ASCII ▼
Shared Secret	••••••
Confirm Shared Secret	••••••
Port Number	1813
Server Status	Enabled ▼
Server Timeout	2 seconds
Network User	<input checked="" type="checkbox"/> Enable
IPSec	<input type="checkbox"/> Enable

Using the CLI

Before creating the radius server, you need to allot an index number to it which is not currently in use. To find out the index numbers which are currently in use in WLC, use the following command

```
show radius summary
```

Go through the authentication servers and accounting servers section in the displayed output. Use an unused index number for adding radius authentication or accounting server.

```
config radius auth add <RADIUS auth server ID> <RADIUS server IP>
1812 ascii <password>
config radius auth disable < RADIUS auth server ID >
config radius auth rfc3576 enable < RADIUS auth server ID >
config radius auth enable < RADIUS auth server ID >
config radius acct add <RADIUS acct server ID > <RADIUS server IP>
1813 ascii <password>
```

Configuring FlexConnect ACLs

1. Select **Security > Access Control Lists > FlexConnect ACLS**. Create a FlexConnect ACL list to allow DNS, DHCP and IPS (Traffic).

The screenshot shows the Cisco Guest Access web interface. The left sidebar has a navigation menu with the following items: AAA, RADIUS, TACACS+, LDAP, Local Net Users, MAC Filtering, Disabled Clients, User Login Policies, AP Policies, Password Policies, Local EAP, Priority Order, Certificate, and Access Control Lists. The 'Access Control Lists' item is expanded, showing sub-items: Access Control Lists, CPU Access Control Lists, and FlexConnect ACLs. The main content area is titled 'Access Control Lists > Edit' and shows a table of rules. The table has columns: Seq, Action, Source IP/Mask, Destination IP/Mask, Protocol, Source Port, Dest Port, and DSCP. There are five rules listed, all with the action 'Permit'.

Seq	Action	Source IP/Mask	Destination IP/Mask	Protocol	Source Port	Dest Port	DSCP
1	Permit	0.0.0.0 / 0.0.0.0	0.0.0.0 / 0.0.0.0	UDP	DHCP Server	Any	Any
2	Permit	0.0.0.0 / 0.0.0.0	0.0.0.0 / 0.0.0.0	UDP	DNS	Any	Any
3	Permit	0.0.0.0 / 0.0.0.0	0.0.0.0 / 0.0.0.0	UDP	Any	DNS	Any
4	Permit	3.3.3.2 / 255.255.255.255	0.0.0.0 / 0.0.0.0	Any	Any	Any	Any
5	Permit	0.0.0.0 / 0.0.0.0	3.3.3.2 / 255.255.255.255	Any	Any	Any	Any

Using the CLI

To see all the ACLs that are configured on the controller enter the following command:

```
show flexconnect acl summary
```

To create a new ACL

```
config flexconnect acl create <ACL name>
```

To create rules in the newly created ACL

```
config flexconnect acl rule add <ACL name> <Rule number1>
```

```
config flexconnect acl rule protocol <ACL name> <Rule number1> 17 #
17 is UDP
config flexconnect acl rule source port range <ACL name> <Rule
number1> 68 68 # 68 is DHCP client port number
config flexconnect acl rule action <ACL name> <Rule number1> permit #
Allow access

config flexconnect acl rule add <ACL Name> <Rule number2>
config flexconnect acl rule protocol <ACL name> <Rule number2> 17
config flexconnect acl rule source port range <ACL name> <Rule
number2> 67 67 # 67 is DHCP server port number
config flexconnect acl rule action <ACL name> <Rule number2> permit

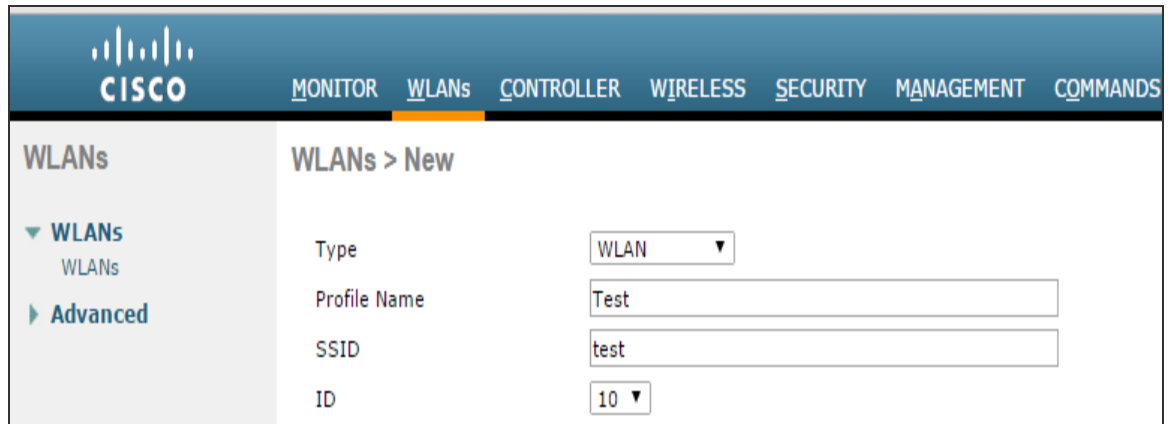

config flexconnect acl rule add <ACL name> <Rule number3>
config flexconnect acl rule protocol <ACL name> <Rule number3> 6
config flexconnect acl rule source port range <ACL name> <Rule
number3> 53 53 # Port 53 for DNS
config flexconnect acl rule action <ACL name> <Rule number3> permit
config flexconnect acl rule add <ACL name> <Rule number4>
config flexconnect acl rule protocol <ACL name> <Rule number4> 6
config flexconnect acl rule destination port range <ACL name> <Rule
number4> 53 53 #port 53 for DNS
config flexconnect acl rule action <ACL name> <Rule number4> permit

config flexconnect acl rule add <ACL name> <Rule number5>
config flexconnect acl rule source address <ACL name> <Rule number5>
<IPS IP> <Subnetmask>
config flexconnect acl rule action <ACL name> <Rule number5> permit

config flexconnect acl rule add <ACL name> <Rule number6>
config flexconnect acl rule destination address <ACL name> <Rule
number6> <IPS IP> <Subnetmask>
config flexconnect acl rule action <ACL name> <Rule number6> permit
```

Configuring WLAN

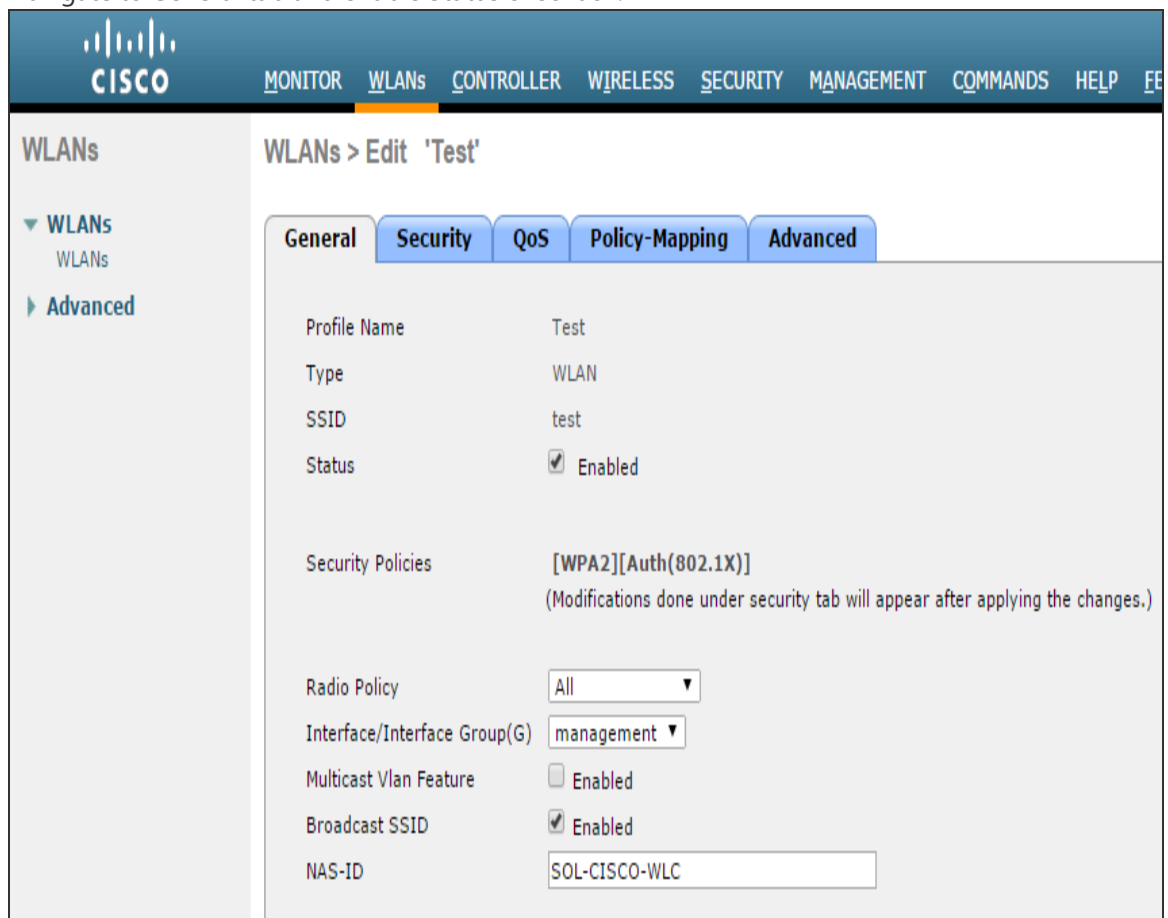

1. Go to WLANs tab and create a new WLAN.

The screenshot shows the Cisco WLAN configuration interface. The top navigation bar includes tabs for MONITOR, WLANs (selected), CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, and COMMANDS. On the left, the 'WLANs' sidebar has options for 'WLANs' and 'Advanced'. The main content area is titled 'WLANs > New' and contains the following fields:

Type	WLAN
Profile Name	Test
SSID	test
ID	10

2. Navigate to General tab and enable Status checkbox.

The screenshot shows the Cisco WLAN configuration interface for editing the 'Test' profile. The top navigation bar includes tabs for MONITOR, WLANs (selected), CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, COMMANDS, HELP, and FEEDBACK. On the left, the 'WLANs' sidebar has options for 'WLANs' and 'Advanced'. The main content area is titled 'WLANs > Edit 'Test'' and features several tabs: General (selected), Security, QoS, Policy-Mapping, and Advanced. The 'General' tab contains the following fields:

Profile Name	Test
Type	WLAN
SSID	test
Status	<input checked="" type="checkbox"/> Enabled
Security Policies	[WPA2][Auth(802.1X)] (Modifications done under security tab will appear after applying the changes.)
Radio Policy	All
Interface/Interface Group(G)	management
Multicast Vlan Feature	<input type="checkbox"/> Enabled
Broadcast SSID	<input checked="" type="checkbox"/> Enabled
NAS-ID	SOL-CISCO-WLC

- Go to Security > Layer 2 in WLAN settings. From the Layer 2 Security drop-down list Select 'None'.

The screenshot displays the Cisco WLAN configuration interface. The top navigation bar includes the Cisco logo and tabs for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, and MANAGEMENT. The left sidebar shows the WLANs configuration tree with options for WLANs and Advanced. The main content area is titled 'WLANs > Edit 'Test'' and features several tabs: General, Security, QoS, Policy-Mapping, and Advanced. Within the Security tab, there are sub-tabs for Layer 2, Layer 3, and AAA Servers. The Layer 2 sub-tab is active, showing a 'Layer 2 Security' dropdown menu set to 'None'. Below this, there is a 'MAC Filtering' checkbox which is unchecked. At the bottom of the Layer 2 section, there is a 'Fast Transition' checkbox, also unchecked.

4. Go to Security > Layer3 in WLANs tab.

- From the Layer 3 security drop-down list select 'Web Policy'.
- For Preauthentication ACL, associate the FlexConnectACL that is created earlier.
- Over-ride Global Config - Select the Enable check box.
- From the Web auth type drop-down list select External (Re-direct to external server)
- URL - Enter the IPS (Guest sign-in URL) for redirection URL.

The screenshot shows the Cisco WLAN configuration interface. The top navigation bar includes links for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, COMMANDS, HELP, and FEEDBACK. The left sidebar shows the WLANs section with a sub-menu for Advanced. The main content area is titled 'WLANs > Edit 'Test'' and features tabs for General, Security, QoS, Policy-Mapping, and Advanced. Under the Security tab, there are sub-tabs for Layer 2, Layer 3, and AAA Servers. The Layer 3 tab is active, showing the Layer 3 Security dropdown set to 'Web Policy'. Below this, there are radio buttons for Authentication (selected), Passthrough, Conditional Web Redirect, Splash Page Web Redirect, and On MAC Filter failure. The Preauthentication ACL section shows IPv4 and IPv6 dropdowns set to 'None' and a WebAuth FlexAcl dropdown set to 'flexpreauthACL'. The Sleeping Client checkbox is unchecked. The Over-ride Global Config checkbox is checked. The Web Auth type dropdown is set to 'External(Re-direct to external server)'. The URL field contains 'https://3.3.3.2/ciscowlc'.

5. Go to **Security > AAA Servers in WLANs** tab. Configure RADIUS server for authentication and accounting.

The screenshot shows the Cisco WLAN configuration interface. The top navigation bar includes tabs for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, MANAGEMENT, COMMANDS, HELP, and FEEDBACK. The left sidebar shows the WLAN configuration tree with 'WLANs' and 'Advanced' options. The main content area is titled 'WLANs > Edit 'Test'' and features several sub-tabs: General, Security, QoS, Policy-Mapping, and Advanced. Under the 'Advanced' tab, there are sub-tabs for Layer 2, Layer 3, and AAA Servers. The 'AAA Servers' sub-tab is active, displaying a section titled 'Select AAA servers below to override use of default servers on this WLAN'. Below this, there are sections for 'Radius Servers' and 'Authentication Servers'. The 'Radius Servers' section includes a checkbox for 'Radius Server Overwrite interface' which is currently unchecked. The 'Authentication Servers' section has a table with columns for 'Authentication Servers' and 'Accounting Servers'. The first row (Server 1) has 'Enabled' checked for both, with IP addresses 'IP:3.3.3.2, Port:1812' and 'IP:3.3.3.2, Port:1813' respectively. Servers 2 through 6 have 'None' selected for both. At the bottom, the 'Radius Server Accounting' section has a checkbox for 'Interim Update' which is checked, and a text field for 'Interim Interval' set to '600'.

Server	Authentication Servers	Accounting Servers
Server 1	Enabled	Enabled
Server 2	None	None
Server 3	None	None
Server 4	None	None
Server 5	None	None
Server 6	None	None

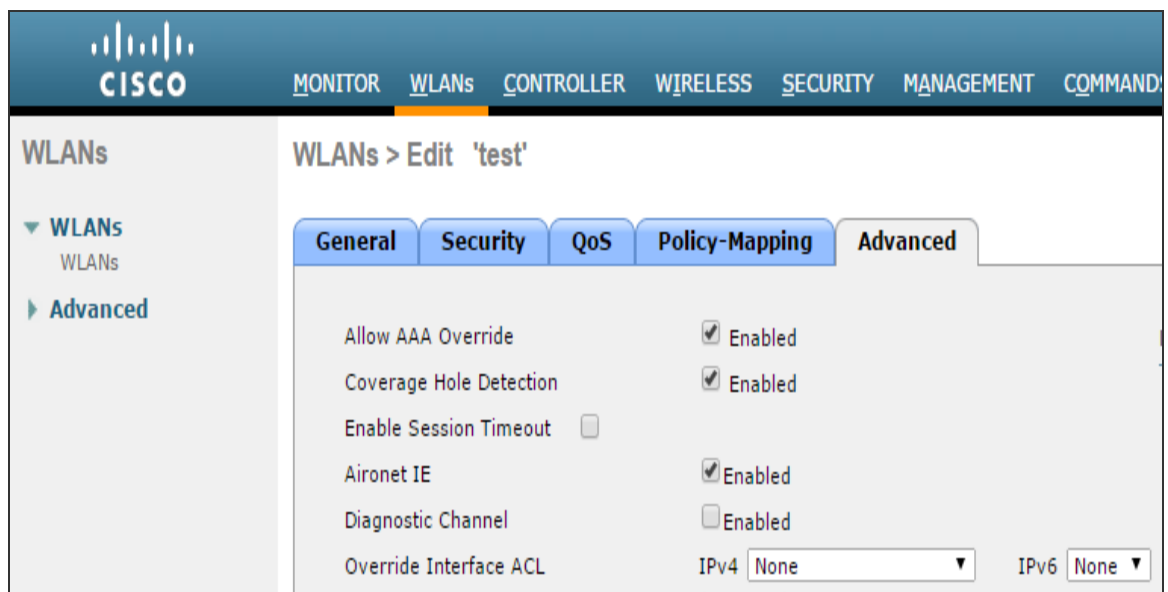

6. Select the **Interim Update** check box.

7. Select **Advanced** tab and enable **Allow AAA Override** checkbox.

The screenshot shows the Cisco WLAN configuration interface for a WLAN named 'Test'. The 'Advanced' tab is selected, and the 'AAA Servers' sub-tab is active. Under the 'Radius Servers' section, the 'Radius Server Overwrite interface' checkbox is checked and labeled 'Enabled'. A red arrow points to this checkbox. Below it, the 'Interface Priority' is set to 'WLAN'. The 'Authentication Servers' and 'Accounting Servers' sections show a table of servers with their respective IP addresses and ports.

Server	Authentication Servers	Accounting Servers
Server 1	IP:3.3.3.2, Port:1812	IP:3.3.3.2, Port:1813
Server 2	None	None
Server 3	None	None
Server 4	None	None
Server 5	None	None
Server 6	None	None

The screenshot shows the Cisco WLAN configuration interface for a WLAN named 'test'. The 'Advanced' tab is selected. The 'Allow AAA Override' checkbox is checked and labeled 'Enabled'. Other settings include 'Coverage Hole Detection' (checked), 'Enable Session Timeout' (unchecked), 'Aironet IE' (checked), 'Diagnostic Channel' (unchecked), and 'Override Interface ACL' (IPv4: None, IPv6: None).

Using the CLI

Before creating a new WLAN verify the existing WLANs on the WLC using the following command and use an unused index id for the new WLAN

```
show wlan summary
```

To create a new WLAN:

```
config wlan create <WLAN_ID> <Profile name> <SSID>
eg: config wlan create 10 Test Test      # Test is the WLAN name and
SSID
config wlan interface <WLAN_ID> <interface-name>
eg: config wlan interface 10 management # assigning the WLAN to
management port
config wlan security wpa disable <WLAN_ID>
config wlan security web-auth enable <WLAN_ID>
config wlan custom-web global disable <WLAN_ID>
config wlan custom-web ext-webauth-url <ext-webauth-url> <WLAN_ID>
config wlan custom-web webauth-type external <WLAN_ID>
config wlan security web-auth flexacl <WLAN_ID> <ACL_name>
config wlan radius_server auth add <WLAN_ID> <Radius_auth_server_ID>
config wlan radius_server acct add <WLAN_ID> <Radius_acct_server_ID>
config wlan radius_server overwrite-interface enable <WLAN_ID> ( This
command is required only if instead of management, some other
interface is configured for WLAN.
Please check steps 2 and 5)
config wlan radius_server acct interim-update enable <WLAN_ID>
config wlan radius_server acct interim-update <Interval> <WLAN_ID>
config wlan aaa-override enable <WLAN_ID>
config wlan enable <WLAN_ID>
```

Configuring AP Group

1. On the CISCO WLC main screen go to **WLANs > Advanced > AP Groups** screen and map WLAN Flexl AP (Remote AP mode) group.

The screenshot shows the Cisco WLC configuration interface for the 'flexgrp' AP group. The left sidebar shows the navigation menu with 'WLANs' and 'Advanced' expanded, leading to 'AP Groups'. The main content area has tabs for 'General', 'WLANs', 'RF Profile', 'APs', and '802.11u', with 'WLANs' selected. A table lists the mapped WLANs:

WLAN ID	WLAN SSID ²	Interface/Interface Group(G)	SNMP NAC State
3	flex	vlan250	Disabled
4	flexdot1x	vlan74	Disabled
7	test	vlan250	Disabled

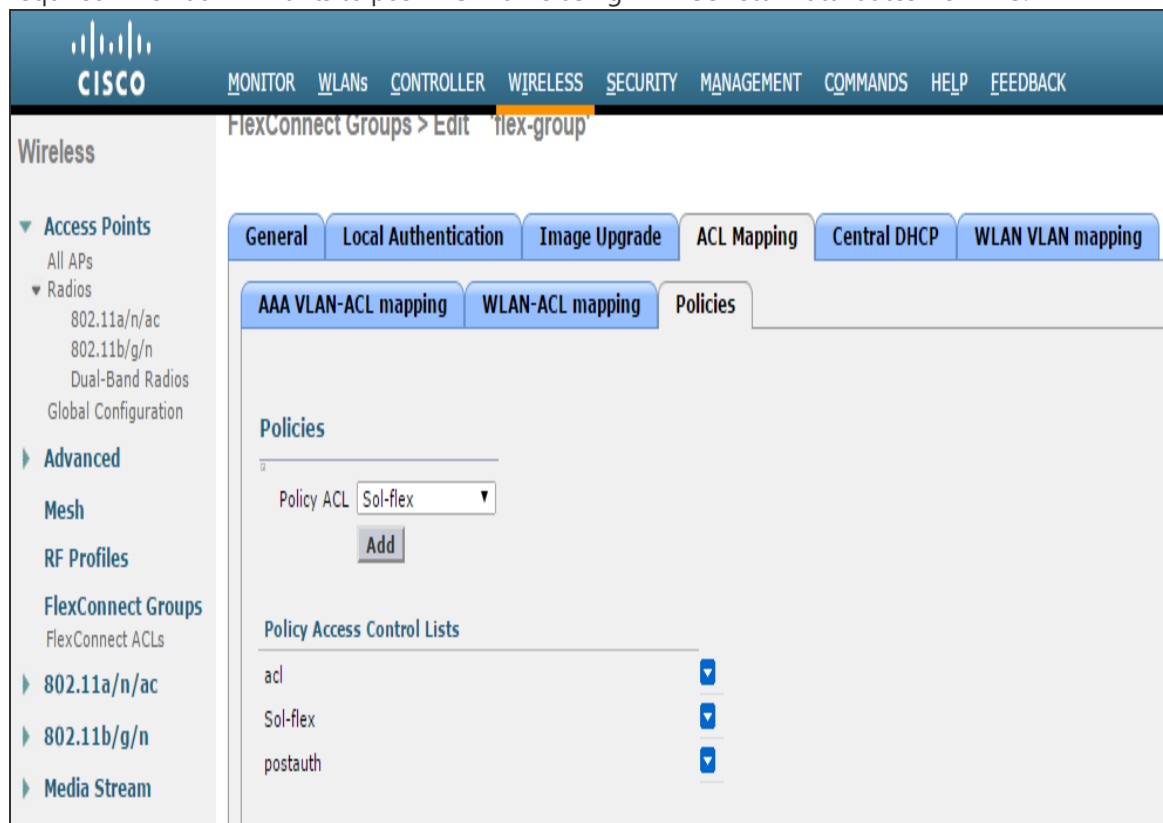

Using the CLI

```
config wlan apgroup interface-mapping add <APgroup Name> <WLAN ID>  
<interfacename>
```

Adding ACLs in FlexConnect Group

To add ACLs in FlexConnect Group:

1. Select **Wireless > FlexConnect Groups**. Click on the required FlexConnect Group and select ACL Mapping > Policies. Add all the required FlexConnect ACLs to this group. This configuration is required when admin wants to push ACL name using RADIUS return attributes from IPS.

Using the CLI

To see all the flexconnect groups that are configured on the controller enter the following command:

```
show flexconnect group summary
```

To add policy ACLs in the flexconnect group use the following command:

```
config flexconnect group <flex-group> policy acl add <flexconnect_
ACL>
```

Save the config using the following command:

```
save config
```

Configuring Cisco 3850 WLC

Configuring Cisco WLC using Web GUI

You can configure CISCO WLC 3850 by performing the steps as stated below:

1. Create a RADIUS server.
2. Create a Radius Server Group and map with the newly created RADIUS server
3. Create an Authentication list and map with the newly created Radius Server Group.
4. Create an Accounting list and map with the newly created Radius Server Group.
5. Create an Authorization list and map with the newly created Radius Server Group.
6. Create a Webauth Parameter Map
7. Create an Access List
8. Create a Sequence Number
9. Create a Wireless SSID

To configure the CISCO WLC 3850:

1. Login to CISCO WLC. The CISCO Wireless Controller home page appears.

The screenshot displays the Cisco Wireless Controller (WLC) home page. The interface is divided into several sections:

- System Summary:** A table providing key system information.

System Time	23:26:47.949 UTC Thu Mar 5 2015
Software Version	03.07.00E RELEASE SOFTWARE (fc4)
System Name	c3850wlc
System Model	WS-C3850-24T
Up Time	2 weeks, 3 days, 20 hours, 0 minutes
Wireless Management IP	10.209.125.128
802.11 a/n/ac Network State	Enabled
802.11 b/g/n Network State	Enabled
Mobility Role	MC
Software Activation	Detail
- Access Point Summary:** A table showing the status of access points.

	Total	Up	Down
802.11a/n/ac Radios	0	0	0
802.11b/g/n Radios	0	0	0
All APs	0	0	0
- Client Summary:** A section for client-related statistics.

[Protocol Statistics](#)

No Protocol Statistics available
- Search:** A search bar with a "Search" button.
- Top WLANs:** A table listing the top WLANs.

Profile Name	Number of Clients
open3850	0
dot1x3850	0
- AVC for WLAN : open3850:** A section for AVC statistics for the selected WLAN.

AVC is not enabled on this WLAN
- Rogue APs:** A table listing rogue access points.

		Detail
Active Rogue APs	0	Detail
Active Rogue Clients	0	Detail
Adhoc Rogues	0	Detail

2. From the **Configuration**, drop-down list select **Security**. The options under the **Security** section are displayed.

The screenshot displays the Cisco Wireless Controller configuration interface. The top navigation bar includes the Cisco logo, the title "Wireless Controller", and a menu with "Home", "Monitor", "Configuration", "Administration", and "Help". The "Configuration" menu is expanded, showing the "Security" option selected. On the left, a sidebar lists the "Security" section with a tree view including AAA, Method Lists (General, Authentication, Accounting, Authorization), Server Groups, RADIUS (TACACS+ Servers, LDAP Servers, Users, Attribute List, MAC Filtering, AP Policy), Local EAP, Wireless Protection Policies, FQDN, ACL, Web Auth, and Local Policies. The main content area is titled "General" and contains the following settings:

- Dot1x System Auth Control: ☒
- Local Authentication:
- Local Authorization:
- Radius-server load-balance method:

3. Select **AAA > Radius > Servers** to create a Radius server. The Radius Server screen appears.

The screenshot displays the Cisco Wireless Controller configuration interface. The left sidebar shows the navigation tree under the 'Security' section, with 'AAA' expanded and 'RADIUS' > 'Servers' selected. A red arrow points to the 'Servers' link. The main content area is titled 'Radius Servers' and contains a table with one entry named 'wiredradius'.

Radius Servers

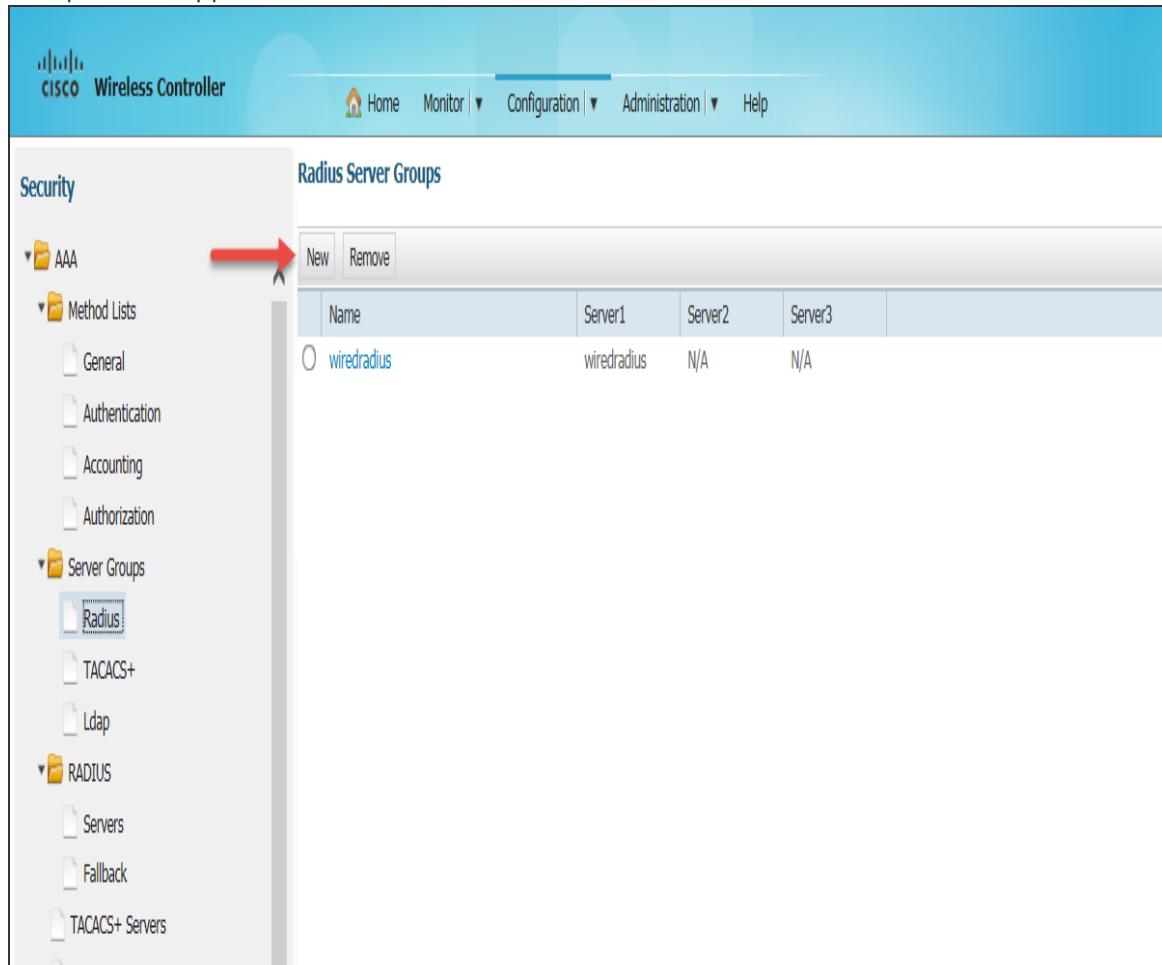

Server Name	Address	Auth Port	Acct Port
wiredradius	10.204.89.165	1812	1813

4. Click **New** to create a Radius server.

The screenshot shows the Cisco Wireless Controller configuration interface. The top navigation bar includes 'Home', 'Monitor', 'Configuration', 'Administration', and 'Help'. The left sidebar shows the 'Security' menu with 'RADIUS' expanded and 'Servers' selected. The main content area is titled 'RADIUS Servers' and 'Radius Servers > New'. It contains a form with the following fields: 'Server Name' (IC165), 'Server IP Address' (10.204.89.165), 'Shared Secret' (masked with dots), 'Confirm Shared Secret' (masked with dots), 'Auth Port (0-65535)' (1645), 'Acct Port (0-65535)' (1646), 'Server Timeout (1-1000)secs' (empty), 'Retry Count (0-100)' (empty), and 'Support for RFC 3576' (Enable). An 'Apply' button is located in the top right corner of the form area.

5. Enter relevant details and click Apply at the right top corner of the page. A new RADIUS server is created.

6. Select **AAA > Server Groups > Radius** to create a Radius Server Group. The Radius Server Groups screen appears.

The screenshot shows the Cisco Wireless Controller configuration interface. The top navigation bar includes 'Home', 'Monitor', 'Configuration', 'Administration', and 'Help'. The left sidebar shows the 'Security' section with a tree view containing 'AAA', 'Method Lists', 'Server Groups', and 'RADIUS'. The 'Radius' option under 'Server Groups' is selected, indicated by a red arrow. The main content area is titled 'Radius Server Groups' and contains a table with the following data:

Name	Server1	Server2	Server3
wiredradius	wiredradius	N/A	N/A

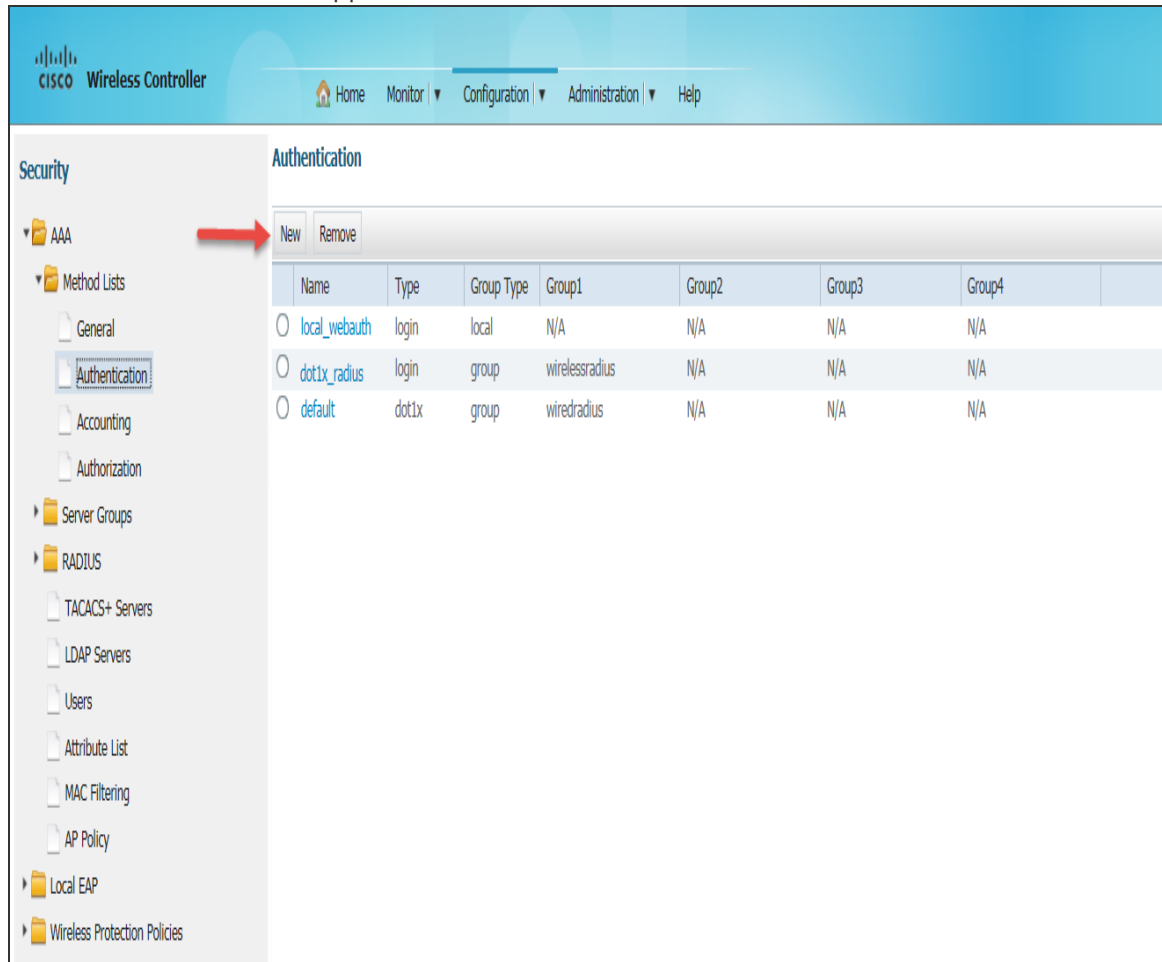

7. Click **New the Radius Server Group > New** screen appears.

The screenshot shows the Cisco Wireless Controller configuration interface for creating a new Radius Server Group. The left sidebar contains a tree view with categories: Security, AAA, Method Lists, Authentication, Accounting, Authorization, Server Groups, and RADIUS. Under Server Groups, 'Radius' is selected. The main content area is titled 'Radius Server Group' with a breadcrumb 'Radius Server Group > New' and an 'Apply' button. The configuration fields include: Name (wirelessradius), MAC-delimiter (none), MAC-filtering (none), Dead-time (0-1440) in minutes (empty), and Group Type (radius). Below these are two boxes: 'Available Servers' containing 'wirelessradius' and 'ic165', and 'Assigned Servers' containing 'ic165'. A button with a right-pointing arrow is between the two boxes. The 'Servers In This Group' label is positioned to the left of the 'Available Servers' box.

8. Enter a name in the Name field. From the Available Servers box select the server which you have created in step 5 and click the button  to move it to the Assigned Servers box.
9. Click Apply to save the Radius Server Group.

10. Select **AAA > Method List > Authentication** to create an Authentication list.

The Authentication screen appears.

The screenshot shows the Cisco Wireless Controller interface. The top navigation bar includes Home, Monitor, Configuration, Administration, and Help. The left sidebar is titled 'Security' and contains a tree view with 'AAA' expanded, showing 'Method Lists' and 'Authentication' selected. A red arrow points to the 'New' button in the 'Authentication' section. The main content area displays a table of authentication methods.

Name	Type	Group Type	Group1	Group2	Group3	Group4
<input type="radio"/> local_webauth	login	local	N/A	N/A	N/A	N/A
<input type="radio"/> dot1x_radius	login	group	wirelessradius	N/A	N/A	N/A
<input type="radio"/> default	dot1x	group	wiredradius	N/A	N/A	N/A

11. Click **New**. The **Authentication > New** screen appears.

The screenshot shows the Cisco Wireless Controller web interface. The top navigation bar includes 'Home', 'Monitor', 'Configuration', 'Administration', and 'Help'. The left sidebar shows the 'Security' menu with options like AAA, Method Lists, Authentication (selected), Accounting, Authorization, Server Groups, RADIUS, TACACS+ Servers, LDAP Servers, Users, Attribute List, MAC Filtering, AP Policy, Local EAP, and Wireless Protection Policies. The main content area is titled 'Authentication > New' and contains the following fields and controls:

- Method List Name:** A text box containing 'webauth_radius'.
- Type:** Radio buttons for 'dot1x' and 'login' (selected).
- Group Type:** Radio buttons for 'group' (selected) and 'local'.
- Fallback to local:** A checkbox that is unchecked.
- Available Server Groups:** A box containing 'wiredradius'.
- Assigned Server Groups:** A box containing 'wirelessradius'.
- Groups In This Method:** A box that is currently empty.

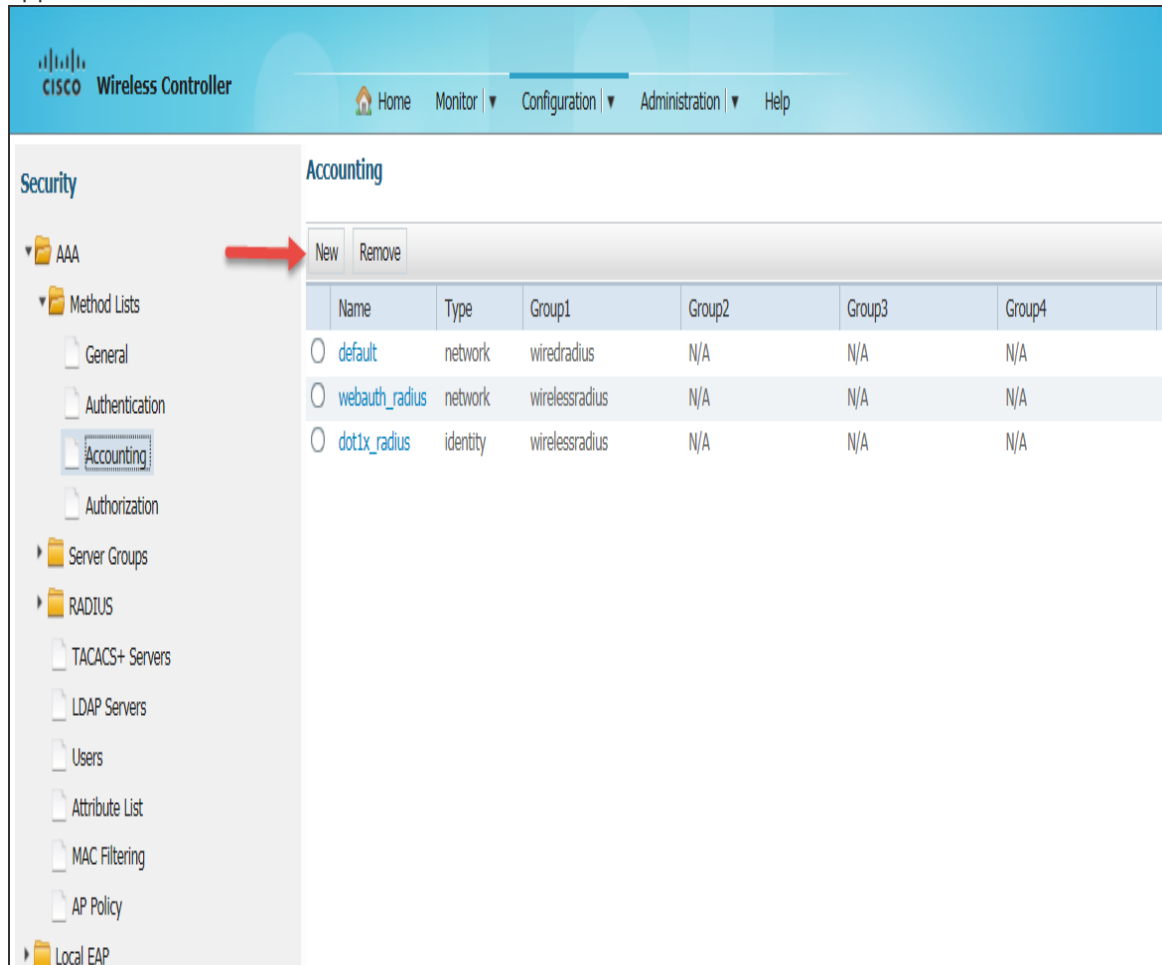

Below the boxes, there is a note: '* Method List Name can be 'default' or any User defined Name.' At the top right of the main area is an 'Apply' button.

12. Enter the details in the fields as follows:

- In the Method List Name field enter webauth_radius
- For Type, select login
- For Group Type select group
- Select the 'wirelessradius' server group that you have created earlier from the Available Server Groups box and click  to move it to the Assigned Server Groups box.

13. Click **Apply** to save the Authentication.

14. Select **AAA > Method List > Accounting** to create an Accounting list. The Accounting screen appears.

The screenshot shows the Cisco Wireless Controller interface. The top navigation bar includes Home, Monitor, Configuration, Administration, and Help. The left sidebar shows the Security section with a tree view containing AAA, Method Lists, and Local EAP. Under Method Lists, the Accounting option is selected. A red arrow points to the 'New' button in the top right of the Accounting section. The main area displays a table of accounting methods.

Name	Type	Group1	Group2	Group3	Group4
<input type="radio"/> default	network	wiredradius	N/A	N/A	N/A
<input type="radio"/> webauth_radius	network	wirelessradius	N/A	N/A	N/A
<input type="radio"/> dot1x_radius	identity	wirelessradius	N/A	N/A	N/A

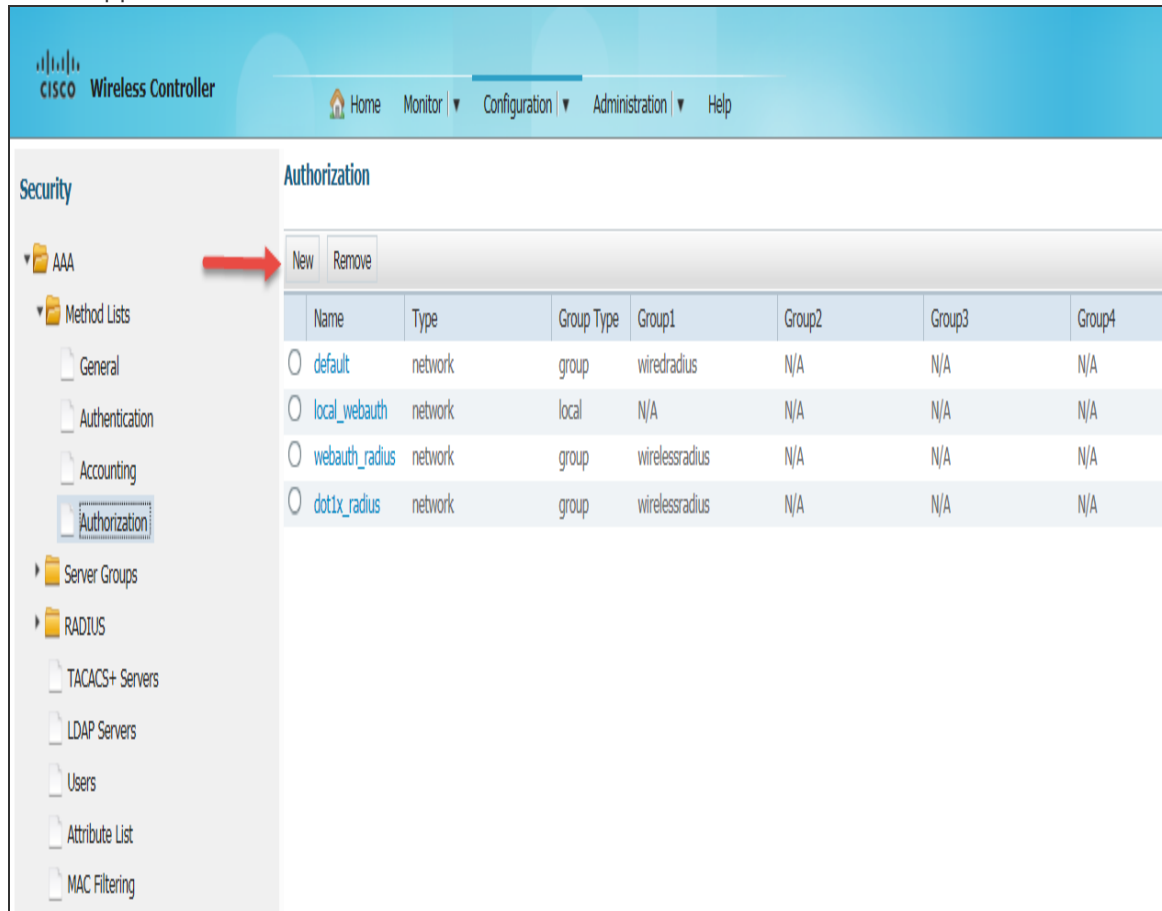

15. Click **New** to create an Accounting list. The **Accounting > New** screen appears.

The screenshot shows the Cisco Wireless Controller web interface. The top navigation bar includes 'Home', 'Monitor', 'Configuration', 'Administration', and 'Help'. The left sidebar shows the 'Security' menu with options like AAA, Method Lists, General, Authentication, Accounting (selected), Authorization, Server Groups, RADIUS, TACACS+ Servers, LDAP Servers, Users, Attribute List, MAC Filtering, AP Policy, Local EAP, and Wireless Protection Policies. The main content area is titled 'Accounting' and 'Accounting > New'. It features a 'Method List Name' field with the value 'webauth_radius', a 'Type' section with radio buttons for 'dot1x', 'exec', 'identity', 'network' (selected), and 'commands', and two boxes for 'Available Server Groups' (containing 'wiredradius') and 'Assigned Server Groups' (containing 'wirelessradius'). A blue arrow button is positioned between these boxes. An 'Apply' button is in the top right corner. A note at the bottom states: '* Method List Name can be 'default' or any User defined Name.'

16. Enter the details in the fields as follows:

- In the Method List Name field enter webauth_radius.
- For Type, select network.
- Select the 'wirelessradius' server group that you have created earlier from the Available Server Groups box and click  to move it to the Assigned Server Groups box.
- Click Apply to save the Accounting list.

17. Select **AAA > Method Lists > Authorization** to create an Authorization list. The Authorization screen appears.

The screenshot shows the Cisco Wireless Controller configuration interface. The left sidebar displays the navigation tree under 'Security', with 'AAA' expanded and 'Method Lists' selected. The 'Authorization' option is highlighted. A red arrow points to the 'New' button in the top right of the main content area. The main content area displays the 'Authorization' screen with a table of existing authorization lists.

Name	Type	Group Type	Group1	Group2	Group3	Group4
<input type="radio"/> default	network	group	wiredradius	N/A	N/A	N/A
<input type="radio"/> local_webauth	network	local	N/A	N/A	N/A	N/A
<input type="radio"/> webauth_radius	network	group	wirelessradius	N/A	N/A	N/A
<input type="radio"/> dot1x_radius	network	group	wirelessradius	N/A	N/A	N/A

18. Click **New** to create an Authorization list. The **New** screen appears.

The screenshot shows the Cisco Wireless Controller interface. The top navigation bar includes 'Home', 'Monitor', 'Configuration', 'Administration', and 'Help'. The left sidebar shows the 'Security' menu with 'Authorization' selected. The main content area is titled 'Authorization' and 'Authorization > New'. It contains the following fields and controls:

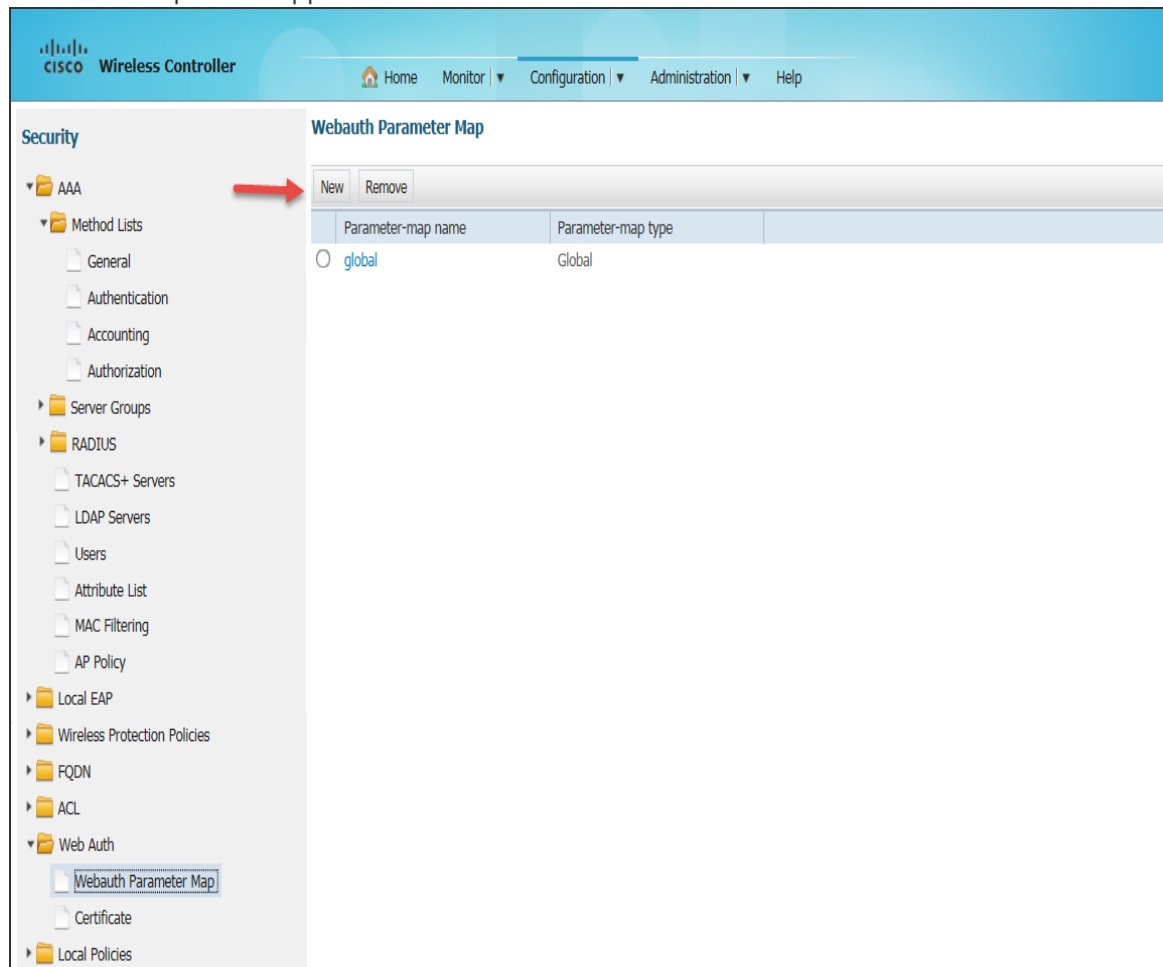

- Method List Name:** A text box containing 'webauth_radius'.
- Type:** Radio buttons for 'network' (selected), 'exec', and 'credential-download'.
- Group Type:** Radio buttons for 'group' (selected) and 'local'.
- Available Server Groups:** A list box containing 'wiredradius'.
- Assigned Server Groups:** A list box containing 'wirelessradius'.
- Groups In This Method:** An empty list box.
- Move Buttons:** A left arrow button and a right arrow button (highlighted with a blue box) between the two server group boxes.
- Apply Button:** A button in the top right corner.
- Footer Note:** '* Method List Name can be 'default' or any User defined Name.'

19. Enter the details in the fields as follows:

- In the Method List Name field enter webauth_radius.
- For Type, select network.
- For Group Type select group.
- Select the 'wirelessradius' server group that you have created earlier from the Available Server Groups box and click  to move it to the Assigned Server Groups box.

20. Click Apply to save the Authorization list.

21. Select Web Auth > Webauth Parameter Map to create a Webauth Parameter Map. The Webauth Parameter Map screen appears.

22. Click **New** to create a Webauth Parameter Map. The **Webauth Parameter Map > New** screen appears.

The screenshot shows the Cisco Wireless Controller configuration interface for creating a new Webauth Parameter Map. The left sidebar shows the navigation tree with 'Webauth Parameter Map' selected under 'Web Auth'. The main configuration area is titled 'Webauth Parameter Map' and includes an 'Apply' button. The configuration fields are as follows:

Field	Value
Parameter-map name	vt_web
Banner	
Maximum HTTP connections(1-200)	30
Init-State Timeout (60-3932100 in seconds)	120
Fin-Wait Timeout (1-2147483647 in millisecond)	3000
Type	webauth
Turn-on Consent with Email	<input type="checkbox"/>
Sleeping-Client	
Status	<input type="checkbox"/> Enabled
Timeout (60-2147483647 in minutes)	
Customized page	
Failed authentication proxy	--Select--
Auth-proxy login parameters	--Select--
Expired authentication proxy	--Select--
Successful authentication proxy	--Select--
Redirect to external server	
Redirect for login	https://10.204.89.165/
Redirect On-Failure	
Redirect On-Success	
Portal IPv4 address	10.204.89.165
Portal IPv6 address	

23. Enter the details in the fields as follows:

- In the Parameter – map name field enter vt_web.
- In Maximum HTTP connections (1-200) enter 30.
- In Init-State Timeout (60-3932100 in seconds) enter 120.
- In Fin-Wait Timeout (1-2147483647 in millisecond) enter 3000.
- In Redirect for login field enter https://10.204.89.165/guest - This is the IPS URL to which a guest is redirected when tried to access a website.
- In Portal IPv4 address enter 10.204.89.165.

24. Click **Apply** to save the Webauth Parameter Map.

A default Webauth Parameter Map is created as shown in the following figure.

The screenshot shows the Cisco Wireless Controller configuration interface for the Webauth Parameter Map. The left sidebar displays the navigation tree under the 'Security' section, with 'Webauth Parameter Map' selected. The main content area is titled 'Webauth Parameter Map' and includes a breadcrumb 'Webauth Parameter Map > Edit'. The configuration is organized into several sections:

- Parameter-map name:** global
- Banner:** (Empty text box)
- Maximum HTTP connections(1-200):** 30
- Init-State Timeout (60-3932100 in seconds):** 120
- Fin-Wait Timeout (1-2147483647 in millisecond):** 3000
- Type:** webauth (dropdown menu)
- Turn-on Consent with Email:** (Unchecked checkbox)
- Virtual IPv4 Address:** 1.1.1.1
- Virtual IPv4 hostname:** (Empty text box)
- Virtual IPv6 Address:** (Empty text box)
- Virtual IPv6 hostname:** (Empty text box)
- Webauth intercept HTTPs:** (Checked checkbox)

Sleeping-Client

- Status:** (Unchecked checkbox) Enabled
- Timeout (60-2147483647 in minutes):** (Empty text box)

29. On the main menu select **Configuration > Wireless to create a Wireless SSID**. The WLANs screen appears.

30. Click **New**. The **WLANs > Create New** screen appears.

31. Click **Apply**. The WLAN is created and displayed in WLANs screen.

The screenshot shows the Cisco Wireless Controller configuration interface. The left sidebar is titled 'Wireless' and contains a tree view with 'WLAN' expanded, showing 'WLANs' as the selected item. The main content area is titled 'WLANs' and features a table with the following columns: Profile, ID, SSID, VLAN, Status, and Security Policies. There are two entries in the table:

Profile	ID	SSID	VLAN	Status	Security Policies
open3850	1	open3850	255	Enabled	Web-Auth
dot1x3850	2	dot1x3850	74	Enabled	[WPA2][Auth(802.1x)]

A red arrow points to the 'open3850' entry in the table.

32. Click the WLAN to configure. The General tab options of the WLAN appears.

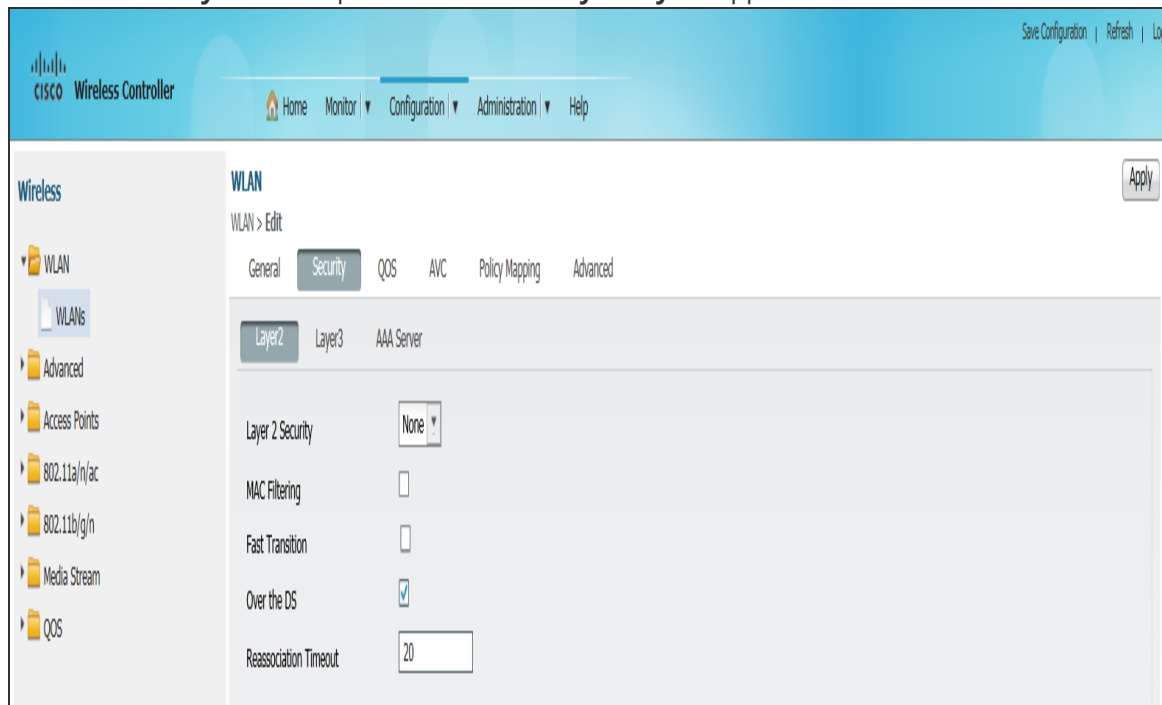

The screenshot shows the Cisco Wireless Controller configuration interface. The top navigation bar includes 'Home', 'Monitor', 'Configuration', 'Administration', and 'Help'. The 'Configuration' tab is selected. On the left, the 'Wireless' menu is expanded, showing 'WLAN' and 'WLANs'. The 'WLAN' configuration page is displayed, with the 'General' tab selected. The configuration details are as follows:

Field	Value
Profile Name	open3850
Type	WLAN
SSID	open3850
Status	<input checked="" type="checkbox"/> Enabled
Security Policies	Web-Auth (Modifications done under security tab will appear after applying the changes.)
Radio Policy	All
Interface/Interface Group(G)	VLAN0255
Broadcast SSID	<input checked="" type="checkbox"/>
Multicast VLAN Feature	<input type="checkbox"/>

An 'Apply' button is located in the top right corner of the configuration area.

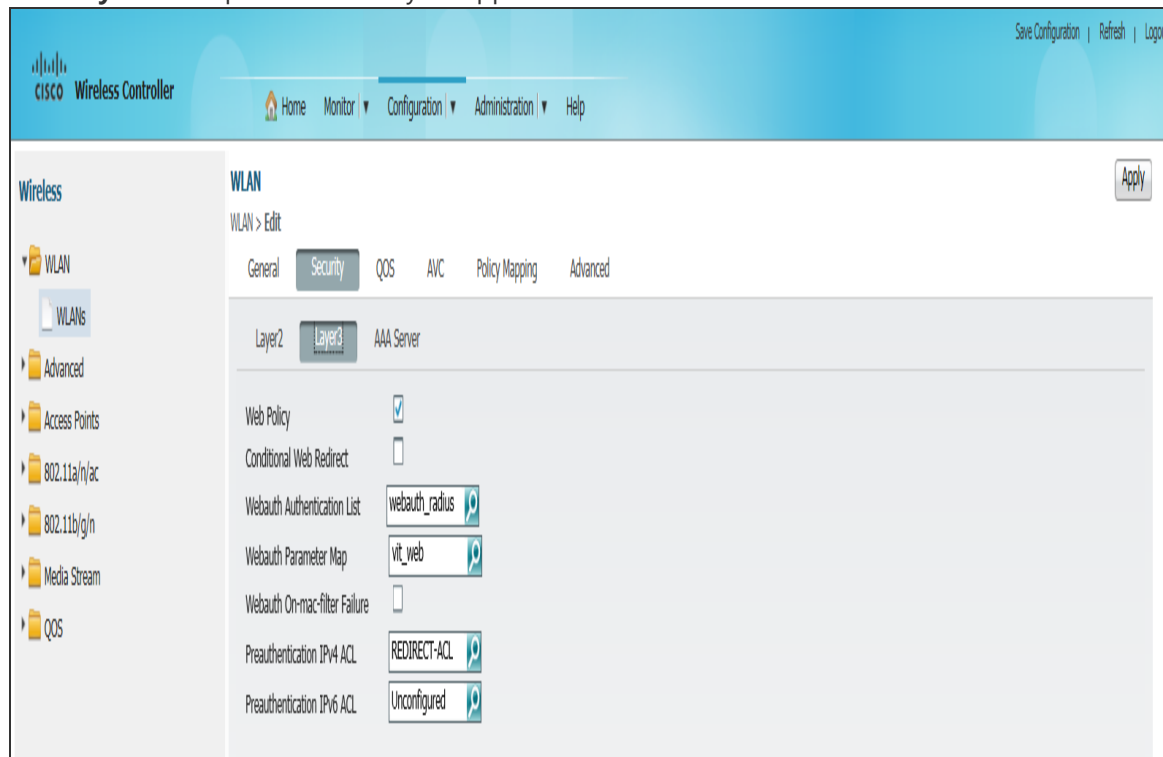

33. Select the options as shown in figure and then click **Apply** to save the configurations.

34. Click the **Security** tab. The options under **Security > Layer2** appears.

35. Select the options as shown in figure and then click Apply to save the configurations.

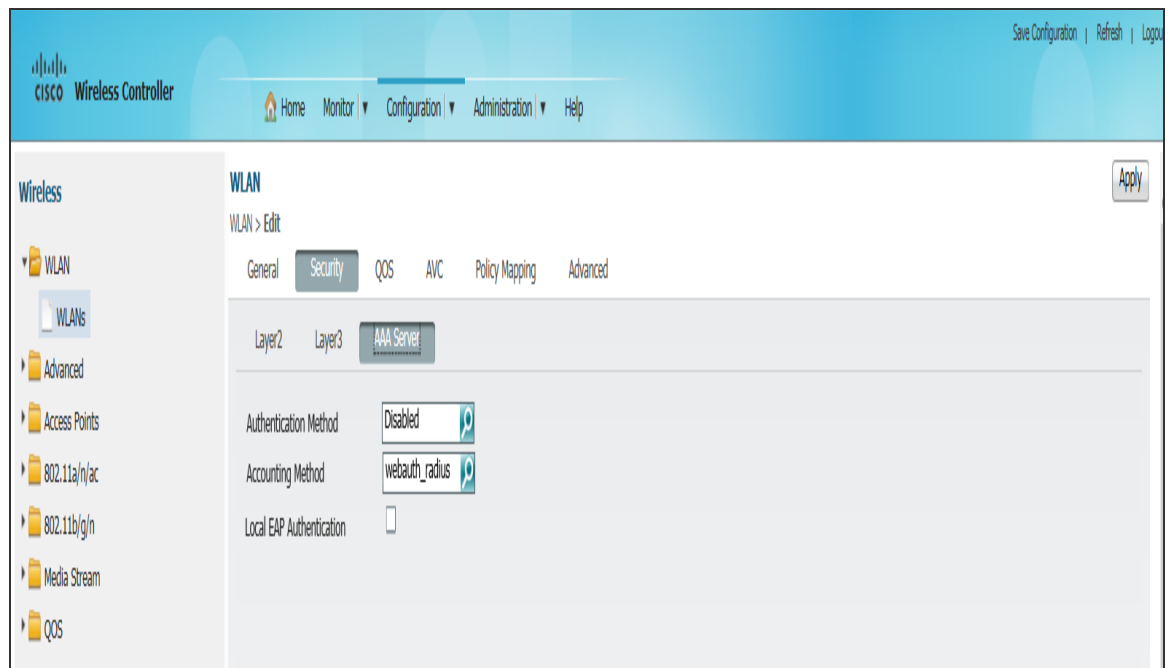

36. Click **Layer3** The options under Layer3 appears.

37. Select the options:
38. For Webauth Authentication List select 'webauth_radius' which you have created earlier.
39. For Preauthentication IPv4 ACL select 'REDIRECT-ACL' which you have created earlier.
40. Click Apply to save the configurations.

41. Click **AAA Server**.

The options under AAA Server appears.

42. From the Accounting Method drop-down list select 'webauth_radius' which you have created earlier. Click **Apply** to save the configurations.

43. Click **Advanced**.

The options under Advanced appears.

44. Select the check box Allow AAA Override, so that radius attribute sent from IPS can be applied. Select other options as shown in the above figure and then click Apply to save the configurations.

Configure WLAN/LANs

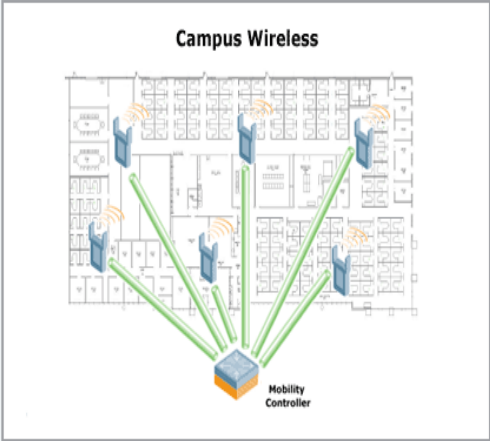

Welcome to the WLAN/LAN Configuration Wizard

Deployment scenario:

☒ Campus Only -- all of the access points will be physically connected to the local controller

☐ Remote Networking -- some of the access points will be deployed at remote locations

Campus Wireless

The diagram illustrates a 'Campus Wireless' network topology. It features a central 'Mobility Controller' represented by a blue and orange cube. Surrounding it is a detailed floor plan of a building. Several access points (APs), shown as blue devices with orange signal waves, are placed at various locations on the floor plan. Green lines connect each AP directly to the central Mobility Controller, indicating a centralized, physical connection for all access points in this deployment scenario.

Begin **Cancel**

2. Select **Campus Only** option and click **Begin**. The Specify Group to Configure screen appears.

The screenshot shows the Aruba Mobility Controller web interface. At the top, the header includes the Aruba logo, 'MOBILITY CONTROLLER | Aruba650', and navigation tabs: Dashboard, Monitoring, Configuration (selected), Diagnostics, Maintenance, Plan, and a Save Configuration button. Below the header, a sub-header reads 'Configure WLAN/LANs'. The main content area is divided into two tabs: '1 Group' (active) and '2 Wireless LANs'. On the left, a vertical sidebar shows a workflow with steps '1 Group to Configure' (highlighted in green) and '2 Finish'. The main panel is titled 'Specify Group to Configure' and contains the following text: 'An AP group is a set of APs that share Wireless LAN parameters. Initially there is a single group named Default. If you wish, you can create multiple groups. [More...](#)'. Below this is a 'Group' dropdown menu set to 'default' and a 'New' button. A note states: 'Note: The setting you select in the Wireless LAN will apply to the Group you select here. If you wish to configure multiple groups you can make multiple passes through Wizards.' At the bottom right, there are 'Next' and 'Cancel' buttons.

3. On Specify Group to Configure screen select an existing AP group or create a new AP group and click **Next**. The Ready to Configure Wireless LANs for Group screen appears.

You can:

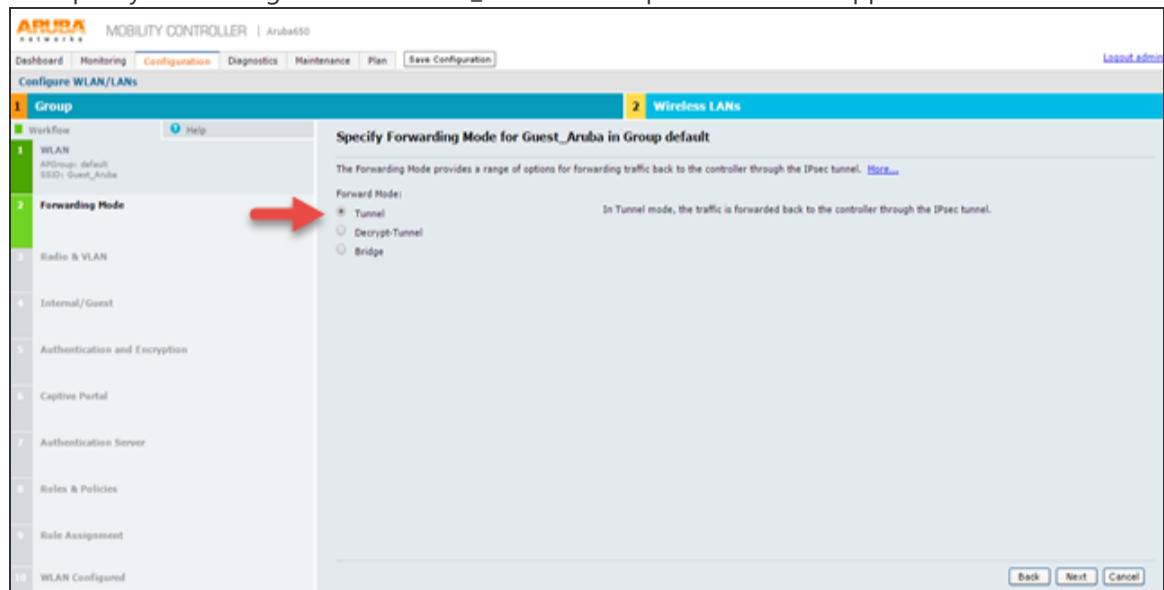

- Select an existing WLAN in Group default
- Create a new WLAN by selecting Group default and clicking **New**
- Create a new WLAN by selecting an existing WLAN in any Group and clicking **Copy**
- Share a new WLAN that belongs to another Group by selecting the WLAN and clicking **Share**

If you are finished, and do not wish to go through the subsequent Wizard steps, click [exit now](#)

Back Next Cancel

5. On Specify Wireless LAN (WLAN) for Group default screen, select a group from the AP Groups list.
6. In the WLANS for list do one of the following:
- Select an existing WLAN.
 - Click **New** to create a new WLAN.
7. Click **Next**.

8. The Specify Forwarding Mode for Guest_Aruba in Group default screen appears.

9. On Specify Forwarding Mode for Guest_Aruba in Group default screen, under Forward Mode, select Tunnel option and click **Next**. The Specify Radio Type and VLAN for Guest_Aruba in Group default screen appears.

The screenshot shows the Aruba Mobility Controller configuration interface. The top navigation bar includes 'Dashboard', 'Monitoring', 'Configuration' (selected), 'Diagnostics', 'Maintenance', and 'Plan'. A 'Save Configuration' button is also present. The main title is 'Configure WLAN/LANs'. The left sidebar shows a workflow with steps 1 through 10. Step 3, 'Radio & VLAN', is currently selected. The main content area is titled 'Specify Radio Type and VLAN for Guest_Aruba in Group default'. It contains a text box with instructions: 'Specify the radio type on which this SSID is available, as well as the VLAN in which users connecting to this SSID are to be placed by default. Note: you can override the VLAN specified below by configuring per-role VLANs in Step 8. [More...](#)'. Below this, there is a 'Radio Type' dropdown menu set to 'all' and a 'VLAN' section with a text input '900', a '<--' button, and another dropdown menu set to '900'. At the bottom right, there are 'Back', 'Next', and 'Cancel' buttons.

10. On Specify Radio Type and VLAN for Guest_Aruba in Group default screen select:
- Radio Type - Select 'all' from the drop-down list.
 - VLAN - Select required options from the drop-down list and click the arrow button to include in the VLAN box.
11. Click **Next**.

12. The Specify whether WLAN is for Internal or Guest use for Guest_Aruba in Group default screen appears.

The screenshot shows the Aruba Mobility Controller web interface. The top navigation bar includes 'Dashboard', 'Monitoring', 'Configuration' (highlighted), 'Diagnostics', 'Maintenance', 'Plan', and a 'Save Configuration' button. A 'Logout admin' link is in the top right. Below the navigation bar is a 'Configure WLAN/LANs' section with two tabs: '1 Group' and '2 Wireless LANs'. The '1 Group' tab is active, showing a workflow on the left with steps 1 through 10. Step 1, 'WLAN', is selected. The main content area is titled 'Specify whether WLAN is for Internal or Guest use for Guest_Aruba in Group default'. It contains a paragraph explaining the difference between Guest and Internal WLANs, followed by the question 'Is this WLAN intended for internal use or for use by guests?'. There are two radio buttons: 'Internal' and 'Guest', with 'Guest' selected. At the bottom right of the main content area are 'Back', 'Next', and 'Cancel' buttons.

The main header is 'Configure WLAN/LANs'. Below this, there are two tabs: '1 Group' (selected) and '2 Wireless LANs'. On the left, a sidebar shows a workflow with steps 1 through 10: 1 WLAN, 2 Forwarding Mode, 3 Radio & VLAN, 4 Internal/Guest, 5 Authentication and Encryption, 6 Captive Portal, 7 Authentication Server (selected), 8 Roles & Policies, 9 Role Assignment, and 10 WLAN Configured. The main content area is titled 'Specify Authentication Server for Guest_Aruba in Group default'. It contains a text block explaining that an enterprise typically uses an external RADIUS server, but the controller has an internal database for small-scale deployments. Below this is an 'Ordered list of Authentication servers' with a table containing one entry 'IC'. To the right of the table are 'Up' and 'Down' buttons. Below the table, there are two radio buttons: 'Select from known servers' (unselected) and 'Specify new server' (selected). Under 'Specify new server', there are fields for 'Server type' (RADIUS selected, LDAP unselected), 'Name' (Guest_RADIUS), 'IP address' (3.3.3.2), 'Auth port' (1812), 'Acct port' (1813), 'Shared keys' (masked with dots), and 'Retype keys' (masked with dots). 'OK' and 'Cancel' buttons are at the bottom of this section. At the bottom right of the main content area, there are 'Back', 'Next', and 'Cancel' buttons.

18. On Specify Authentication Server for Guest_Aruba in Group default screen, specify IPS server as the authentication server and click **Next**.

19. The Specify Roles & Policies for Guest_Aruba in Group default screen appears.

Commands [View Commands](#)

2. Click the RFC 3576 Server and add IPS as RFC 3576 server, for supporting disconnect messages.

- Click on the RFC server that is newly created to provide the key.

The screenshot shows the Aruba Mobility Controller web interface. The top navigation bar includes 'Dashboard', 'Monitoring', 'Configuration' (highlighted), 'Diagnostics', 'Maintenance', and a 'Save Configuration' button. The left sidebar lists various configuration categories: WIZARDS, AP, Controller, Campus WLAN, Remote AP, WIP, AirWave, NETWORK, Controller, VLANs, Ports, Cellular Profile, IP, SECURITY, Authentication (highlighted), and Access Control. The main content area is titled 'Security > Authentication > Servers'. Below this, there are tabs for 'Servers', 'AAA Profiles', 'L2 Authentication', 'L3 Authentication', 'User Rules', and 'Advanced'. The 'Servers' tab is active, displaying a list of server types: Server Group, RADIUS Server, LDAP Server, Internal DB, Tacacs Accounting Server, TACACS Server, XML API Server, and RFC 3576 Server. The 'RFC 3576 Server' is selected, and the configuration page for 'RFC 3576 Server > 3.3.3.2' is shown. This page has a 'Key' field with a text input and a 'Retype:' field with a text input, both containing masked characters (dots).

- Select **Security > Authentication > AAA Profiles**. Go to AAA profile and click on RFC 3576 server. Add the server that is newly created in step1.

The screenshot displays the Aruba WLC Configuration interface. The top navigation bar includes tabs for Dashboard, Monitoring, Configuration (selected), Diagnostics, Maintenance, and Plan, along with a 'Save Configuration' button. The left sidebar contains a navigation menu with categories: WIZARDS (AP Wizard, Controller Wizard, WLAN/LAN Wizard, License Wizard, WIP Wizard), NETWORK (Controller, VLANs, Ports, Uplink, IP), SECURITY (Authentication selected, Access Control), WIRELESS (AP Configuration, AP Installation), and MANAGEMENT (General, Administration, Certificates, SNMP, Logging, Clock, Guest Provisioning, Captive Portal, SMTP, Disks).

The main content area is titled 'Security > Authentication > Profiles'. It features sub-tabs: Servers, AAA Profiles (selected), L2 Authentication, L3 Authentication, User Rules, and Advanced. Under the 'AAA Profiles' tab, a list of profiles is shown on the left, including Aruba_Dot1X-aaa_prof, Aruba_Guest-aaa_prof, default, default-dot1x, default-dot1x-psk, default-mac-auth, default-open, default-xml-api, Dot1x_Aruba-aaa_prof, Guest-aaa_prof, Guest-qatest-aaa_prof, Guest_Aruba-aaa_prof, and RFC 3576 server (selected).

The right pane provides a detailed view of the 'RFC 3576 server' profile. It includes a table with the following data:

RFC 3576 servers	
Name	
3.3.3.2	

Below the table, there is an 'Add a profile' section with a dropdown menu showing '10.204.50.112' and an 'Add' button.

WLAN Configuration for Remote Networking mode on Aruba WLC

1. Log in to Aruba WLC. Select **Configuration > Wizards > WLAN/LAN Wizard**. The **Welcome to the WLAN/LAN Configuration Wizard** screen appears.

ARUBA networks | MOBILITY CONTROLLER | Aruba650

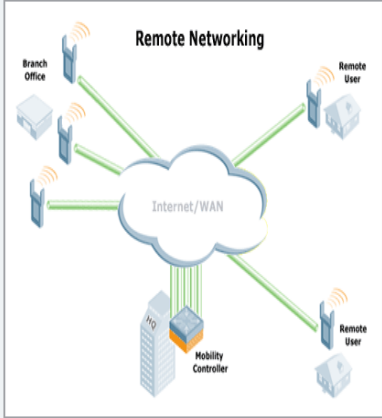

Dashboard | Monitoring | **Configuration** | Diagnostics | Maintenance | Plan | [Save Configuration](#) | [Logout admin](#)

Configure WLAN/LANs

Welcome to the WLAN/LAN Configuration Wizard

Deployment scenario:

- ☐ Campus Only -- all of the access points will be physically connected to the local controller
- ☒ Remote Networking -- some of the access points will be deployed at remote locations

The diagram, titled "Remote Networking", illustrates a network architecture. At the bottom center is a "Mobility Controller" connected to an "HQ" building. Above them is a cloud labeled "Internet/WAN". To the left, a "Branch Office" contains two access points connected to the cloud. To the right, two "Remote User" devices are also connected to the cloud. Green lines represent network connections between the access points, the cloud, and the remote users.

[Begin](#) [Cancel](#)

2. Select Remote Networking option and click **Begin**.

3. The **Specify Group to Configure** screen appears.

The screenshot shows the Aruba Mobility Controller web interface. At the top, the header includes the Aruba logo, 'MOBILITY CONTROLLER | Aruba650', and navigation tabs: Dashboard, Monitoring, Configuration (selected), Diagnostics, Maintenance, Plan, and a Save Configuration button. A Logout admin link is in the top right. Below the header, a breadcrumb trail reads 'Configure WLAN/LANs'. The main content area is divided into two sections: '1 Group' (highlighted in blue) and '2 Wireless LANs' (highlighted in grey). On the left, a 'Workflow' sidebar shows '1 Group to Configure' (highlighted in green) and '2 Finish'. The main panel is titled 'Specify Group to Configure'. It contains a description: 'An AP group is a set of APs that share Wireless LAN parameters. Initially there is a single group named Default. If you wish, you can create multiple groups. [More...](#)'. Below this is a 'Group' dropdown menu with 'qa-remote' selected and a 'New' button. A note states: 'Note: The setting you select in the Wireless LAN will apply to the Group you select here. If you wish to configure multiple groups you can make multiple passes through Wizards.' At the bottom right, there are 'Next' and 'Cancel' buttons.

4. On the **Specify Group to Configure** screen, select an AP group and click **Next**.

The screenshot shows the Aruba Mobility Controller configuration interface. The top navigation bar includes 'Dashboard', 'Monitoring', 'Configuration' (selected), 'Diagnostics', 'Maintenance', and 'Plan'. A 'Save Configuration' button is also present. The main content area is titled 'Configure WLAN/LANs' and has three tabs: '1 Group' (selected), '2 Wired LANs', and '3 Wireless LANs'. On the left, a workflow pane shows four steps: '1 Group to Configure' (selected), '2 RAP DHCP Settings', '3 RAP DNS Query Routing', and '4 Finish'. The main panel is titled 'Specify RAP DHCP Settings for Group qa-group'. It contains a text block explaining that each remote AP has a DHCP server and provides a link for more information. Below this, there is a checkbox labeled 'Use internal DHCP server' which is checked and highlighted by a red arrow. Underneath the checkbox are several input fields: 'DHCP pool start' (192.168.11.2), 'DHCP pool end' (192.168.11.254), 'DHCP pool netmask' (255.255.255.0), 'Default router' (192.168.11.1), 'DNS server' (empty), 'VLAN ID' (192), and 'DHCP Lease time' (radio buttons for 'Limit to: 30 Days' and 'No Limit', with 'No Limit' selected). At the bottom right, there are 'Back', 'Next', and 'Cancel' buttons.

5. On the **Specify RAP DHCP settings for Group qa-group** screen, configure:

- DHCP pool start
- DHCP pool end
- DHCP pool netmask
- Default router
- DNS server
- VLAN ID
- DHCP Lease time – Select the required option and set the limit.

6. Click **Next**.

The **Specify RAP DNS Query Routing for Groups qa-group** screen appears.

The screenshot shows the Aruba Mobility Controller configuration interface. At the top, there's a navigation bar with tabs: Dashboard, Monitoring, Configuration (selected), Diagnostics, Maintenance, Plan, and a Save Configuration button. A Logout admin link is on the right. Below the navigation bar, the main heading is "Configure WLAN/LANs". There are three tabs: 1 Group (selected), 2 Wired LANs, and 3 Wireless LANs. On the left, a workflow pane shows four steps: 1 Group to Configure (selected), 2 RAP DHCP Settings, 3 RAP DNS Query Routing, and 4 Finish. The main content area is titled "Specify RAP DNS Query Routing for Group qa-group". It contains a paragraph explaining that parameters are relevant for split-tunnel forwarding mode and that domains are resolved by the corporate DNS server. A checkbox labeled "DNS query routing" is present and unchecked. At the bottom right, there are three buttons: Back, Next, and Cancel.

```

Configuring Aruba Instant Access Point

To configure Aruba Instant Access Point:

1. Login to the Aruba Instant Access portal. The Aruba Instant page appears.

The screenshot displays the Aruba Instant Access portal for a virtual controller named 'instant-C3:21:A8'. The interface is divided into several sections:

- Top Bar:** Includes the Aruba Networks logo, 'Virtual Controller', and the controller name 'instant-C3:21:A8'. Navigation links for System, RF, Security, Maintenance, More, Help, and Logout are present.
- Summary Cards:** Three cards at the top show '1 Network', '1 Access Point', and '0 Clients'. The '1 Network' card lists 'iap205' with a 'New' link highlighted by a red arrow.
- Info Panel:** Located on the bottom left, it provides details for the virtual controller: Name (instant-C3:21:A8), Country code (IN), Virtual Controller IP (10.209.125.123), Management (Local), Master (10.209.122.124), Uplink type (Ethernet), and Uplink status (Up).
- RF Dashboard:** The central section with tabs for Signal, Speed, Utilization, Noise, and Errors. It shows 'All clients' and 'All access points' with corresponding status indicators.
- Usage Trends:** On the bottom right, it features two graphs: 'Clients' (a line graph showing 0 clients over time) and 'Throughput (bps)' (a stacked area chart showing Out and In traffic).
- Footer:** Includes a language dropdown set to 'English', the 'Aruba Central' logo, and a 'Pause' button.

2. Click **New** to create a new SSID. The New WLAN window appears.

The screenshot shows the Aruba Networks Instant-View interface. On the left, there's a sidebar with the Aruba logo and 'Virtual Controller' text. Below it, a table titled '1 Network' lists networks with columns 'Name' and 'Clients'. The first entry is 'iap205' with 0 clients. Below the table is a section for 'instant-C3:21:A8' with system information: Name, Country code (IN), Virtual Controller IP (10.209.125.123), Management (Local), Master (10.209.122.124), Uplink type (Ethernet), and Uplink status (Up). The main window is titled 'New WLAN' and has four tabs: '1 WLAN Settings' (highlighted in green), '2 VLAN', '3 Security', and '4 Access'. The 'WLAN Settings' tab contains the following fields: 'Name (SSID):' with a text box containing 'Guest_iap', 'Primary usage:' with three radio buttons: 'Employee', 'Voice', and 'Guest' (which is selected). At the bottom of the tab, there is a link 'Show advanced options' and two buttons: 'Next' and 'Cancel'.

3. In the WLAN Settings tab:
4. In the New (SSID) field enter a name for the SSID.
5. In the Primary usage options select **Guest**.
6. Click **Next**.

7. The VLAN tab options appears.

8. Keep the DHCP setting as per your network design.
9. Client IP assignment here Network Assigned is chosen.
10. For Client VLAN assignment here **Default** is chosen
11. Click **Next**.

12. The Security tab options appear.

The screenshot shows the 'New WLAN' configuration window with the 'Security' tab selected. The 'Security Level' section is active, displaying a list of settings on the left and a detailed configuration panel on the right. The configuration panel is titled 'New' and contains the following fields:

- Splash page type: External (dropdown)
- Captive portal profile: New (dropdown)
- WISPr: New
- MAC authentication: Name: cap (text field)
- Auth server 1: Type: Radius Authentication (dropdown)
- Reauth interval: IP or hostname: 10.204.89.165 (text field)
- Internal server: URL: /guest (text field)
- Blacklisting: Port: 443 (text field with clear button)
- Walled garden: Use https: Enabled (dropdown)
- Disable if uplink type is: Captive Portal failure: Deny internet (dropdown)
- Encryption: Automatic URL Whitelisting: Disabled (dropdown)
- Redirect URL: (text field) (optional)

At the bottom of the configuration panel are 'OK' and 'Cancel' buttons. At the bottom of the main window are 'Back', 'Next', and 'Cancel' buttons.

In the Security Level section do the following:

1. From the Security page type, drop-down list select External.
2. From the Captive portal profile, drop-down list select New
3. The **New** screen appears.
4. Enter the details as shown in the above figure and then click OK.

5. The newly created captive portal appears in the Captive portal profile drop-down list.

The screenshot displays the 'New WLAN' configuration window with the 'Security Level' tab selected. The 'Auth server 1' dropdown is set to 'New', which has triggered a 'New Server' dialog box. In the dialog, the 'RADIUS' option is selected. The fields are populated as follows: Name: 'ic', IP address: '10.204.89.165', Auth port: '1812', Accounting port: '1813', Shared key: '*****', Retype key: '*****', Timeout: '5' sec., Retry count: '3', RFC 3576: 'Enabled', Air Group CoA port: '5999'. Optional fields for NAS IP address, NAS identifier, Dead time (5 min.), and various DRP fields are also present. The background window shows 'Splash page type' as 'External', 'Captive portal profile' as 'cap', 'WISPr' as 'Disabled', and 'MAC authentication' as 'Disabled'. Navigation buttons 'Back', 'Next', and 'Cancel' are visible at the bottom right of the main window.

6. From the Auth server 1 drop-down list select New.
7. The New Server screen appears.
8. Create a server pointing to IPS server. Enter the details as shown in figure and then click OK.

9. The configured Security tab options appear as in the following figure.

The screenshot shows the 'New WLAN' configuration window with the 'Security' tab selected. The window has a blue header with 'New WLAN' and a 'Help' link. Below the header is a tab bar with four tabs: '1 WLAN Settings' (orange), '2 VLAN' (green), '3 Security' (green), and '4 Access' (grey). The 'Security' tab is active, showing the 'Security Level' section. The configuration options are as follows:

- Splash page type: External (dropdown)
- Captive portal profile: cap (dropdown) with an 'Edit' button
- WISPr: Disabled (dropdown)
- MAC authentication: Disabled (dropdown)
- Auth server 1: ic (dropdown) with an 'Edit' button
- Auth server 2: -- Select Server -- (dropdown)
- Reauth interval: 0 min. (dropdown)
- Accounting: Use authentication servers (dropdown)
- Accounting mode: Authentication (dropdown)
- Accounting interval: min. (dropdown)
- Blacklisting: Disabled (dropdown)
- Walled garden: [Blacklist: 0](#) [Whitelist: 0](#)
- Disable if uplink type is: ☐ 3G/4G ☐ Wifi ☐ Ethernet
- Encryption: Disabled (dropdown)

At the bottom right, there are three buttons: 'Back', 'Next', and 'Cancel'.

10. Click **Next**. The Access tab options appear.

Configuring Ruckus WLC

Ruckus WLC is configured as Radius Client where IPS is the Radius Server. Figure illustrates the workflow of Guest Access on IPS for Ruckus WLC. This section provides examples of how to configure the Ruckus WLC. For more information, see *Ruckus documentation*.

To configure Ruckus WLC with IPS:

1. Connect user/endpoint to the Ruckus Wireless network with open SSID over 802.1X with restricted access through ACLs.
2. Redirect Ruckus WLC guest to external (IPS) captive portal when guest tries to access a web-resource.
3. Enter credentials on captive portal page.
4. For guest access authentication, IPS provides guest user credentials to Ruckus SmartZone WLC's management interface via REST API.
5. Ruckus WLC can encode the credentials and send it to a RADIUS server (IPS) through Radius Access Request.

6. The RADIUS server validates the credentials and sends a RADIUS response, which contains standard RADIUS attributes and Vendor Specific Attributes.
7. Ruckus WLC provides network access to the guest by changing VLAN based on IPS role-based policy.

Ruckus SmartZone WLC Configuration

The Ruckus SmartZone software platform provides unified software architecture across wireless LAN (WLAN) controllers, for appliance, virtualized and cloud environments for deployment flexibility.

To configure SmartZone WLC:

1. Configure IPS as Radius Sever.
2. Select **Configuration > AP Zone > Zone Name > AAA servers> Create New**.
3. Configure Name, IP Address, Shared Secret and Confirm Secret.

The screenshot displays the Ruckus SmartZone WLC Configuration interface. The top navigation bar includes the Ruckus logo, a timestamp (2016/03/14 14:40:57), and user information (Administration Domain, admin, Super Admin, My Account, Log Off). The main navigation tabs are Dashboard, Monitor, Configuration, Report, Identity, Device, and Administration. The left sidebar lists various configuration options, with 'AAA' highlighted under the 'Configuration' section. The main content area shows the 'AAA Servers' configuration page, which includes a table of existing servers and a 'Create New AAA Server' form. The form is divided into two sections: 'General Options' and 'Primary Server'. The 'General Options' section contains fields for Name (Radius Server), Description, Type (RADIUS, RADIUS Accounting, Active Directory, LDAP), and Backup RADIUS (Enable Secondary Server). The 'Primary Server' section contains fields for IP Address (10.204.88.139), Port (1812), Shared Secret, and Confirm Secret. The form has 'OK' and 'Cancel' buttons at the bottom.

To configure Hotspot (WISPr) service:

1. Select **Configuration > AP Zone > Zone Name > Hotspot (WISPr) > Create New**.

The screenshot shows the Ruckus Virtual SmartZone - High Scale (SmartZone) configuration interface. The left sidebar contains a navigation menu with the following items: Zone Configuration, AP Group, AAA, Hotspot (WISPr) (highlighted), WeChat, Guest Access, Web Authentication, Hotspot 2.0, WLAN, WLAN Scheduler, Device Policy, L2 Access Control, Bonjour Gateway Policies, DiffServ, Ethernet Port, Global Configuration, and AP Tunnel Profiles. The main content area is titled 'Create New Hotspot Portal' and contains the following sections:

- General Options:**
 - Portal Name: * HotSpot
 - Portal Description:
- Redirection:**
 - Smart Client Support:
 - ☒ None
 - ☐ Enable
 - ☐ Only Smart Client Allowed
 - Logon URL:
 - ☐ Internal
 - ☒ External
 - Redirect unauthenticated user to the URL for authentication. *
 - Redirected MAC Format: * (format used for including client's MAC inside redirected URL request)
 - Start Page:
 - ☒ After user is authenticated, Redirect to the URL that user intends to visit.
 - ☐ Redirect to the following URL:
 - *
- User Session**
- Location Information**
- Walled Garden**

At the bottom of the form are 'OK' and 'Cancel' buttons.

2. Configure Portal Name, Logon URL text box with https://IPS-ip/guest.

3. Configure Northbound Interface password as Ruckus Request Password on Radius Client page in IPS.

The screenshot shows the Ruckus Virtual SmartZone - High Scale (SmartZone) web interface. The top navigation bar includes the Ruckus logo, a timestamp (2016/03/23 21:30:58), and user information (Administration Domain | admin | Super Admin | My Account | Log Off | ?). The main navigation menu has tabs for Dashboard, Monitor, Configuration (selected), Report, Identity, Device, and Administration. The left sidebar lists various configuration options, with 'Northbound Portal Interface' highlighted. The main content area is titled 'Northbound Portal Interface' and contains a description: 'Set the northbound portal interface password. 3rd party applications use the northbound portal interface to authenticate users and to retrieve user information during the UE association.' Below this, there is a 'Password:' label, a text input field containing eight asterisks, and three buttons: 'Refresh', 'Apply', and 'Cancel'.

To configure WLAN:

1. Select **Configuration > AP Zone > Zone Name > WLAN > Create New**.
2. Configure Name, SSID, Authentication type as "Hotspot (WIPSr) ", Authentication Method as "open" and Encryption as "None".

3. Select Hotspot configured from drop down list and select Authentication Server.

Verifying Device Certificates

Ruckus device certificate validation enhances the security between IPS and the Ruckus device for guest access. It allows IPS to verify whether the server certificate is from a trusted source. This topic describes how to configure the IPS for validating device certificates, create certificates on Ruckus, and check the validity of the certificate.

Step1: Creating a Server Certificate

To create a CSR:

1. From Certificate Server generate a Server Certificate with private key and import the certificate on Ruckus SmartZone.
2. To import the certificate on Ruckus, select **Configuration > System > Certificate Store > Import**.

The screenshot shows the Ruckus Virtual SmartZone - High Scale (SmartZone) Configuration page. The left sidebar contains a menu with options like General System Settings, System Time, Syslog Server, Northbound Portal Interface, SMTP Server, FTP Server for Uploading Statistical Data, Critical AP Rules, Manage User Agent Blacklist, Node Affinity, Certificate Store, Cluster & Planes, Cluster Planes, Cluster Redundancy, Network Management, SNMP Agent, Event Management, Event Threshold, and Management Interface ACL. The main content area is titled 'Configuration > System > Certificate Store'. It displays a table of certificates with columns for Name, Status, Type, and Date. Below the table is an 'Edit Certificate' dialog for 'Ruckus-SZ'. The dialog includes fields for Name, Description, and a large text area for the certificate details. Below the text area are fields for Server Certificate, Intermediate CA certificate, and Root CA certificate, each with a 'Browse' button. There are also fields for Private Key (with an 'Upload' button) and Key Phrase.

Step2: Importing the Certificate on IPS

To import the certificate on IPS:

1. Obtain the root CA from the certificate server for the generated certificate.
2. Select **System > Configuration > Certificates > Trusted Server CAs > Import Trusted Server CA** and import the certificate.

Step3: Adding Ruckus Wireless device as RADIUS Client

To add Ruckus wireless device to IPS:

1. Select **Endpoint policy > Network Access > RADIUS Client > New RADIUS Client**.
2. Select Ruckus Wireless as a Radius client and enable Ruckus Server Certificate Validation.
3. (Optional) From client machine, perform a guest authentication, if the guest user is able to authenticate then the certificate is valid. Otherwise it is an invalid certificate or certificate is not available.
4. (Optional) Verify the event logs to check if there are any certificate invalid logs.

Cisco Meraki WLC Configuration

The following steps give configuration of Cisco Meraki WLC:

1. Configure IPS as Radius Sever.
2. Select **Wireless > Access Control > Select SSID**.
3. Configure Radius Authentication and Accounting Server for the Splash page.

Policy Name:

☒ Windows ☐ Mac ☐ Linux ☐ Solaris

▼ Rule Settings

- Enter the rule name and specify the criteria for compliance and click **Save Changes**.

Configuration > Host Checker Policy > Add Predefined Rule : Firewall

Add Predefined Rule : Firewall

Rule Type: Firewall

*Rule Name:

▼ *Criteria

☐ Require any supported product.
☒ Require specific products/vendors
☒ Require any supported product from a specific vendor.

Available Vendors:

Selected Vendors:

☐ Require specific products

▼ Optional

☐ Monitor this rule for change in result

Note: Enabling this option will report change in compliance for this rule to the Pulse Policy Secure immediately. The client component requires additional computing cycles to report change in compliance immediately. We strongly recommend that this option be enabled for rules that are dynamic in nature, for example a rule for RTP check provided by AntiVirus software. For other rules the host checker update frequency should be used to get periodic health checks from endpoints.

▼ Remediation

Click on the remediation column headers to see the list of Firewalls supporting remediation

For Remediation Role, ensure that the Host Checker not required option is not selected.

1. Set Role Mapping rules. Select **User Realms > Guest > Role Mapping > New Rule**.

The image shows two side-by-side screenshots from a web application.

The left screenshot is the 'Role Mapping Rule' configuration page. It has a breadcrumb trail: 'User Realms > Guest > Role Mapping > Role Mapping Rule'. The title is 'Role Mapping Rule'. Below it, 'Rule based on:' is set to 'Custom Expressions' with an 'Update' button. The '* Name:' field contains 'HC Pass'. A green message says 'Rule: If user has any of these custom expressions...'. There are two lists: 'Available Expressions' (containing 'HC Fail' and 'HC Pass') and 'Selected Expressions' (empty). Between them are 'Add ->', 'Remove', and 'Expressions ...' buttons. Below these is a section 'then assign these roles' with 'Available Roles' (containing 'ENGG', 'Guest', 'Guest Admin', 'Guest Sponsor', 'Guest Wired Restricted', and 'Limited Access Role') and 'Selected Roles' (containing 'FullAccessRole'). Between them are 'Add ->' and 'Remove' buttons. At the bottom, there is a checkbox 'Stop processing rules when this rule matches' and a link 'To manage roles, see the Roles configuration page.' At the very bottom are 'Save Changes' and 'Save + New' buttons.

The right screenshot is a browser window titled 'Guest Authentication Server Catalog - Google Chrome'. The address bar shows 'Not secure | [redacted]/dana-admin/auth/serverDict.cgi'. The page title is 'Server Catalog for Guest Authentication'. There are two tabs: 'Expressions' (active) and 'Variables'. Under 'Expressions', 'View:' is set to 'HC Pass'. The 'Name:' field contains 'HC Pass'. The 'Expression:' text area contains 'hostCheckerPolicy = 'Firewall Policy''. At the bottom are 'Save Changes', 'Close', and 'Delete' buttons. On the right side, there is an 'Expressions Dictionary' panel with a tree view containing 'Prebuilt Expressions', 'Your Expressions', 'Logical Operators', 'Your Variables', and 'Variables'. The 'Variables' section is expanded, showing 'anomalyType', 'callingStationId', 'certAttr' (set to 'C'), and 'certAttr.allName' (set to 'directoryName'). At the bottom of this panel is a '< Insert Expression' button.

Once the role mapping rules are configured the following screen is displayed.

User Realms > Guest > Role Mapping

Role Mapping

Creating a new RADIUS Client

Add the Switch as RADIUS client

1. Select **Endpoint Policy > Network Access > RADIUS Client**.
2. Enter the name.
3. Enter the IP address of the Switch.
4. Select the make/model as Huawei.
5. Select the default location group as Guest.
6. Click **Save Changes**.

Shared Secret will be used in the Huawei/RADIUS configuration.

Configuring RADIUS Return Attribute Policies

Define Radius Return Attribute policy based on ACL for different roles.

1. Set RADIUS return attributes. Select **Endpoint Policy > Network Access > RADIUS Return Attribute Policies**. Click **New Policy**.

2. Under RADIUS Attributes tab, select the check box for **Return Attribute**. Select appropriate Vendor Specific Attribute as Return Attribute. In the Value filed, define the ACL/Firewall Filter. For example, Return Attribute is **Filter-Id** and Value as **full_access.in**.

Network Access > Radius Attributes > RADIUS Return Attributes > Guest Access Policy

Guest Access Policy

General

* Name: Required: Label to reference this policy.

Description:

Location Group

Specify the Location Group for which this policy applies.

Available Location Groups:

Selected Location Groups:

Selected Radius Clients

Below list is populated dynamically based on the selected Location Groups

Vendor (Manufacturer)	Client Details
Huawei	HUAWEL_WLC_RADIUS_CLIENT

Access Control Policy Settings

Select below option to control the access level for the device/user connecting to the network

☐ Provide full Access (Open Port)

☒ Control the Access

Note: Selecting this option will result in opening the port without any restrictions

Note: Selecting this option enables control of the device or user access

Access can be controlled using the VLAN Id, ACLs and Radius Return Attribute settings below

☒ Control using VLAN Id: (1 - 4094)

Specify the PPS interface to which end points will connect while they are assigned to above VLAN

☒ Automatic ☐ Internal ☐ External

Note: This option is used for assigning devices to corresponding VLAN on the switch

☐ Control access using Access Control List (ACL) settings (Supported only for Cisco, Juniper, HP)

☒ Control access using Radius Return Attributes

Note: These attributes are sent to switch for controlling the access

Return Attribute	Radius Auth Server Attribute Value	Auth Server Catalog Attribute Value	Value	
<input type="checkbox"/> Filter-Id	<input type="text" value="-none-"/>	<input type="text" value="-none-"/>	<input type="text" value=""/>	<input type="button" value="Add"/>
<input type="checkbox"/> Filter-Id	<input type="text" value="-none-"/>	<input type="text" value="-none-"/>	<input type="text" value="full_access.in"/>	

☐ Add Session-Timeout attribute

Specify the action that needs to be taken for the device upon expiration of session timeout on the switch

☒ Terminate the session ☐ Re-authenticate the session

Note: This will send session timeout attribute equal to session lifetime

Roles

Select the roles to which this policy is applicable

☐ Any Role ☒ Selected below ☐ Other than selected below

Available roles:

Selected roles:

NOTE: Any changes to this page results in termination of existing L2 connections and triggers reconnections.

Similarly define a remediation policy with Return Attribute as **Filter-Id** and Value as **limited_access.in**.

Network Access > Radius Attributes > RADIUS Return Attributes > Limited Access Role

NOTE: Any changes to this page results in termination of existing L2 connections and triggers reconnections.

The following example shows the Filter-Id radius attribute policy for Huawei Switches.

Network Access > Radius Attributes > RADIUS Return Attributes

RADIUS Return Attributes

RADIUS Dictionary RADIUS Vendor Location Group RADIUS Client **RADIUS Attributes** Network Infrastructure Device SNMP Enforcement Policies

Return Attributes Request Attributes Attribute Logging

Show policies that apply to: All roles

A RADIUS return attributes policy specifies the return list attributes to send to an 802.1X network access device, such as which VLAN endpoints must use to access the network. If no policy applies, Open Port is the default action.

		Policies	ACL Settings	Attributes	Location Group	Interface	Applies to role
<input type="checkbox"/>	1.	Limited Access Role This role will be applied when the guest endpoint does not meet the security policies	N/A	VLAN=201 Filter-Id=limited_access.in	Guest	AUTO	Remediation
<input type="checkbox"/>	2.	Guest Access Policy This policy will be applied when Guest role is applied	N/A	VLAN=101 Filter-Id=full_access.in	Guest	AUTO	Guest

Keyboard shortcuts:
Use "<" and ">" keys to move selected items up and down (remember to click Save Changes after rearranging the list). Use **Ctrl+Plus** and **Ctrl+Minus** to expand and collapse all items.

The following example shows RADIUS return attribute used to send the VLAN ID. In the below example, VLAN 101 is sent for Guest Access Role and VLAN 201 for Limited Access Role.

The following example shows the Filter-Id radius attribute policy for Huawei Switches.

- When using VSAs there is no need to configure ACL/Firewall filters in the switches. These are managed by IPS and access control entries (ACEs) will be applied on the switches after User Authentication.
- VLAN change using CoA is supported with Huawei Switches.

Configuring Huawei WLC/Switch

Administrator must configure hw_redirect_url as redirect url parameter key and hw_login_url as key for the login url parameter on Huawei switch.

```

Example Configuration: Guest Access with Juniper Mist WLC

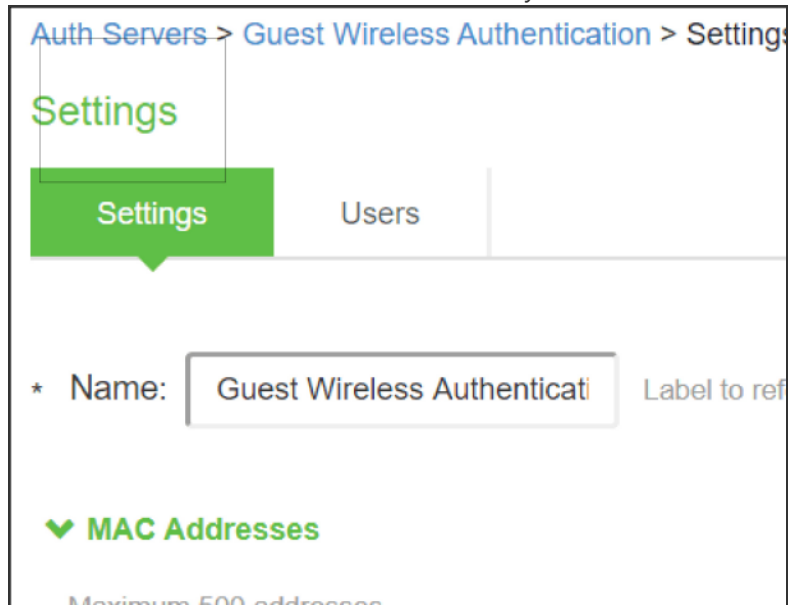

This section describes the configuration that is required on IPS to communicate with Juniper Mist WLC for Guest wireless authentication.

To configure IPS for guest wireless authentication:

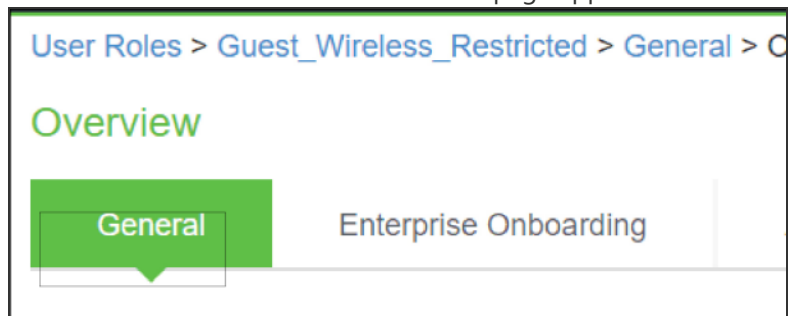

1. Select **Authentication > Auth.Servers**. The Authentication Servers screen appears. Use the Default Guest Wired Authentication Server.

2. Click Guest Wired Authentication available by default to view the settings.

3. You can make the necessary changes and click **Save Changes**.
4. Select Users > User Roles. The User Roles page appears.

5. Click Guest Wired Restricted user role available by default. The Agentless access is enabled for this role.

6. Select **Endpoint Policy > MAC Address Authentication Realms** and click Guest Wired authentication realm available by default.

The screenshot shows the 'MAC Address Realms > Guest_Wireless > General' configuration page. The 'General' tab is active, showing fields for Name (Guest_Wireless), Description, and a checkbox for 'When editing, start on the Role Mapping page'. Below this is the 'Servers' section with a table for Authentication, User Directory/Attribute, Accounting, and Device Attributes. The 'Authentication' dropdown is set to 'Guest Wireless Authentication'. The 'Dynamic policy evaluation' section has a checkbox for 'Enable dynamic policy evaluation'. The 'Other Settings' section shows 'Authentication Policy' and 'Role Mapping' both set to 'No restrictions' and 'No Rules'. A 'Save Changes' button is at the bottom.

Authentication	User Directory/Attribute	Accounting	Device Attributes
Guest Wireless Authentication	Same as above	None	None

7. Select **Endpoint Policy > Network Access > Location Group**. Select Guest Wired as MAC Auth Realm.
8. Configure the Mist WLC as a RADIUS client. Ensure that the Guest Wired location group and Support Disconnect Messages options are enabled.

The screenshot shows the 'Network Access > RADIUS Client > Mist' configuration page. The 'RADIUS Client' section is active, showing fields for Name (Mist), Description, IP Address (10.96.78.49), IP Address Range (1), Shared Secret, Make/Model (Mist Systems), and Location Group (Guest_Wireless). The 'Dynamic Authorization Support' section has checkboxes for 'Support Disconnect Messages' (checked), 'Support CoA Messages', and 'Dynamic Authorization Port' (3799). A 'Save Changes' button is at the bottom.

- Configure the RADIUS return attributes for Guest Wired policy. Select **Endpoint Policy > Network Access > RADIUS Return Attribute Policies**. Click **New Policy**. Under RADIUS Attributes tab, select the check box for **Return Attribute**. The RADIUS return attributes are required for MAB authentication initially when the guest connects to the SSID (where the redirection happens) and then the session is bridged after the guest authenticates.

Supported Attributes: Filter-Id, Airspace-ACL-Name, Aruba-User-Role.

Cisco-AVPair is supported to set the redirection URL.

Tunnel-Private-Group-ID and Airespace-Interface-Name are used to assign the VLANs.

Policies	ACL Settings	Attributes	Location Group	Interface	Applies to role
1. Guest Wireless Radius Redirection Attributes User is given a Guest Wired Role when initial authentication happens.	N/A	Cisco-AuthProxy-RedirectURL Cisco-AuthProxy-RedirectURL=https://10.99.78.25/guest?ClientMacAddr=cmacgstrat987 Tunnel-Private-Group-ID=74	Guest Wired	N/A	Guest Wired Restricted
2. Guest Radius Return Attributes User is given a Guest Role when Guest Wired L2 session and L3 browser session gets bridged.	N/A	Filter-Id=Full_Access Tunnel-Private-Group-ID=60	Guest Wired	N/A	Guest

Configuring Mist WLC

To configure WLAN on Mist:

- Add Mist as Access Point.

Status	Name	MAC Address	IP Address	No. Clients	Uptime	Total Bytes	Capabilities	VLAN
Disconnected	0	0 B
Connected	Juniper_Mist_AP	...	10.10.10.10	1	2d 2h 58m	1.3 GB

- Setup the Wireless Networks, Select **Network > WLANs**. Click **Add WLAN**.
- Configure Name, SSID.
- Under Security, select **Open Access**.
- Enable **Guest Access with Mac Authentication Bypass**.

6. Under RADIUS Authentication Server and RADIUS Accounting Server, specify the IPS IP address.

The screenshot shows the Mist Pulse Secure configuration interface for a WLAN named 'mist_automation'. The left sidebar contains navigation options like Monitor, Clients, Access Points, Location, Analytics, and Network. The main content area is divided into several sections:

- WLAN Status:** Includes SSID (mist_automation), Labels (mist_automation), and Radio Band (2.4G and 5G).
- Band Steering:** Includes Client Inactivity (Drop inactive clients after 1800 seconds).
- Geo-fence:** Includes Minimum client RSSI (-50 dBm) and Minimum client RSSI (dBm).
- Data Rates:** Includes Compatible (allow all connections), No Legacy (2.4G, no 11b), High Density (enable all lower rates), and Custom Rates.
- WiFi Protocols:** Includes WiFi 6 (Enabled).
- WLAN Rate Limit:** Includes Limit uplink to (10 Mbps) and Limit downlink to (20 Mbps).
- Per-Client Rate Limit:** Includes Limit uplink to (512 Kbps) and Limit downlink to (1 Mbps).
- Application Rate Limit:** Includes Enabled (Enabled).
- Security:** Includes WPA-2/PSK with passphrase (mist_automation), WPA-2/PSK with multiple passphrases, and WPA-2/PSK with multiple passphrases.
- RadSec:** Includes Enabled (Enabled) and RADIUS Authentication Servers (10.96.78.25:1812).
- RADIUS Accounting Servers:** Includes 10.96.78.25:1813.
- NAS Identifier:** Includes NAS IP Address (10.96.78.49).
- Co/AM Server:** Includes Enabled (Enabled) and IP Address (10.96.78.25).
- VLAN:** Includes Static VLAN ID (999) and Dynamic VLAN ID (60, 63, 74, 192).
- Guest Portal:** Includes No portal (go directly to Internet), Custom guest portal, Forward to external portal, and SSID with identity provider.

7. Create Security Policy to control resource access.

The screenshot shows the Mist Pulse Secure Policy configuration interface. The left sidebar contains navigation options like Monitor, Clients, Access Points, Location, Analytics, and Network. The main content area is divided into several sections:

- Policy:** Includes Site Policies (site Primary Site).
- Site Policies:** Each user/resources session is evaluated according to the list of Policy rules. The policy for the first matching rule is applied.

No.	User (matching all labels)	Policy	Resource (matching all labels)	Usage (No. Sessions)
1	Language: all labels	✓	facebook	264
2	United states	✓	facebook	0
3	us_34	✓	All Resources	0
4	us_34	✓	All Resources	0
Last	All Users	✓	All Resources	

8. You can also issue a label. The label is used to form tags or groups, which can be used to create security policies.

The screenshot displays the Mist Pulse Secure web interface. On the left is a blue sidebar with navigation icons and labels: Monitor, Marvis™, Clients, Access Points, Location, Analytics, Network, and Organization. The main content area is titled 'PULSE SECURE' and shows the configuration for a label named 'Limited-attr'. At the top right of the main area, there are buttons for 'Delete Label', 'Save', and 'Cancel'. The configuration is divided into three sections: 'Label Name' with a text input containing 'Limited-attr'; 'Label Type' with a dropdown menu set to 'AAA Attribute' and a note 'This is a User label if used in WxLan'; and 'Label Values' with a 'User Group' dropdown set to 'User Group' and a 'User Group Values' text area containing 'Limited'. A green 'IS' icon is visible next to the 'Label Values' section. At the bottom of the 'Label Values' section, a note states 'Note: Requires newer firmware'.

Enterprise Onboarding

Overview

Ivanti Policy Secure(IPS) Enterprise Onboarding feature automatically configures and provisions mobile and personal devices running on platforms such as Windows, MAC OSX, Android, and iOS. It enables them to securely connect to the enterprise network in support for Bring Your Own Device (BYOD) initiatives.

The onboarding provides a way to configure Wireless, VPN, and device certificate profiles on a device. Using these profiles the users can securely connect to enterprise network and access enterprise resources. The profiles can be configured on a single IPSIPS server dedicated to onboarding or on each server.

The supported profiles depend on the device type and whether the Ivanti Secure Access Client is installed.

For enterprise onboarding a separate license called *"Advanced Mobile Licenses – Onboarding"* is required.

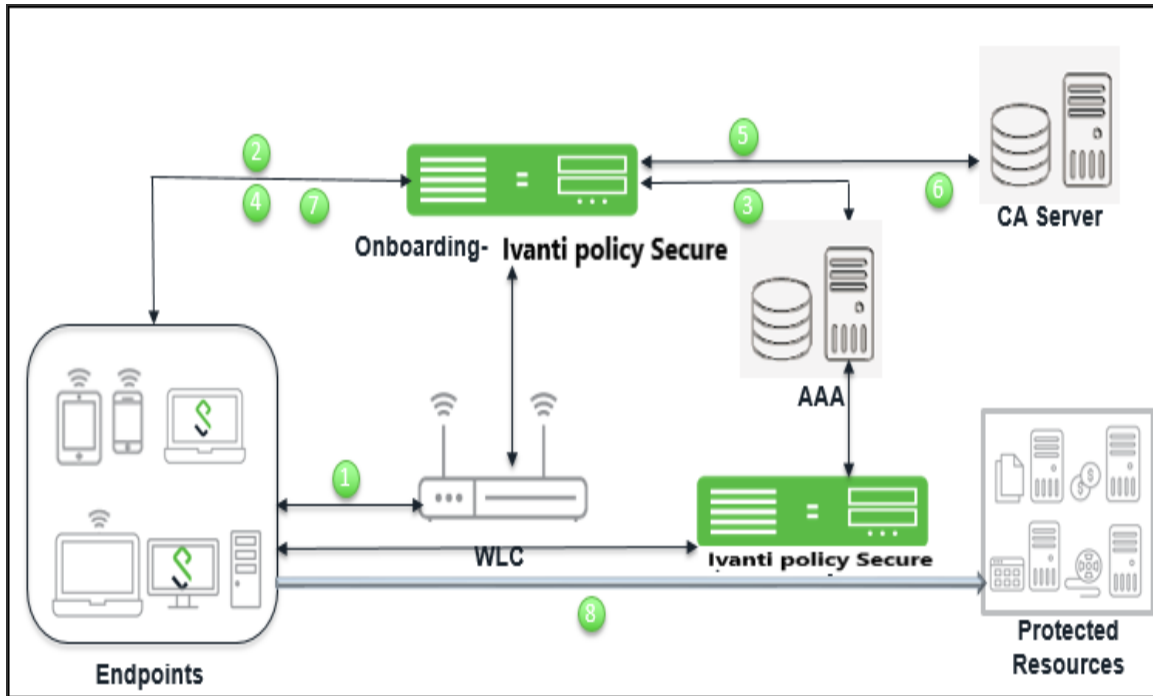

- Android platform supports all profiles. However, Ivanti Secure Access Client application must be installed during onboarding.
- iOS platform supports all profiles through Safari browser.
- Windows platform supports Wi-Fi and certificate profiles (IE, Firefox, or Chrome browser). The Ivanti Secure Access Client onboarding application must be installed during onboarding. Windows 8 RT and Windows 8 Phone are not supported.
- MAC OSx platform supports Wi-Fi and certificate profiles (Safari browser).

You can see more information on the supported platforms in the Supported Platform document.

You can also define the profiles on an external MDM server. If an external MDM server is used, the user will see a link and instructions on the onboarding page to continue onboarding. Onboarding is initiated from the browser.

Deployments

Enterprise Onboarding allows users to securely access enterprise network resources with any device. Wi-Fi, VPN and certificate profiles can be defined and downloaded to a device during onboarding, depending on the device type. The deployment diagram illustrates how a BYOD user can get onboarded through IPS to connect to enterprise network and access enterprise resources.

The workflow for enterprise onboarding is described below:

1. User tries to connect to enterprise network using the BYOD.
2. WLC is configured with Captive portal, which redirects the user to IPS login page where the devices can be onboarded.
3. User is authenticated through AAA framework.
4. User is provided with an onboarding link.
5. To generate and provision device certificate, IPS submits CSR to CA server.
6. CA server signs the CSR and sends the certificate to IPS.

7. Ivanti Policy Secure(IPS) pushes the configured profiles to devices.
8. User logins and access the network.

Configuring Enterprise Onboarding

This section covers the configuration for enterprise onboarding. It involves configuring the profiles, SCEP server and CSR templates.

Configuring Enterprise Onboarding for a User Role

Enterprise onboarding is enabled in the user role, and each profile can be applied to all user roles or specific roles. The SCEP server and CSR templates allow certificates to be generated dynamically for device and server authentication.

To enable enterprise onboarding for a user role:

1. In the admin console, choose **Users > User Roles > RoleName > General > Overview**.
2. In the Enterprise Device Onboarding section, select the **Enterprise Onboarding** check box.
3. Click **Save Changes**.

4. Click the **Enterprise Onboarding** tab or click **Options** next to the **Enterprise Onboarding** check box to specify the following:
 - **Auto launch** – Displays the onboarding page when the user logs in to IPS if enterprise onboarding is enabled for the user's role (the default). If this option is disabled, an onboarding link is displayed on the home page.
 - **Install Ivanti Secure Access Client** – Select this option to automatically install Ivanti Secure Access Client during windows onboarding.
 - **Use third party MDM for onboarding** – Displays a link on the onboarding or home page where the user can download profiles from an MDM server. Enter the URL for the MDM page in the text box.

The screenshot shows the 'Enterprise Onboarding > Options' configuration page. At the top, there is a breadcrumb trail: 'User Roles > Users > Enterprise Onboarding > Options'. Below this, the 'Options' title is displayed in green. A tabbed interface is present with four tabs: 'General', 'Enterprise Onboarding' (which is highlighted in green), 'Agent', and 'Agentless'. Under the 'Enterprise Onboarding' tab, there is a section titled 'Options' with a green header bar. Below this, there are three configuration items, each with a checkbox icon on the left: 1. 'Auto launch' with a description: 'Use this to automatically push Enterprise Onboarding profile configurations to the device when user logs in'. 2. 'Install Pulse Secure client' with a description: 'Use this to automatically install Pulse Secure client during onboarding from Windows OS. With this option enabled, you must also enable "Pulse Secure client" option [here](#) for the changes to take effect.' 3. 'Use third party MDM for Onboarding' with a description: 'Redirect to MDM URL' followed by a text input field. At the bottom left of the configuration area is a blue button labeled 'Save Changes'.

5. Click **Save Changes**.

Configuring the SCEP Server

The Simple Certificate Enrollment Protocol (SCEP) server configuration and CSR templates allows each client device to dynamically obtain certificates for authentication. The SCEP server and CSR templates allow certificates to be generated dynamically for device and server authentication.

To define the SCEP server:

1. Select **Users > Enterprise Onboarding**.
2. Click **SCEP Configuration**.

Enterprise Onboarding > SCEP Configuration

SCEP Configuration

SCEP Configuration | CSR Templates | VPN Profiles | WIFI Profiles | Certificate Profiles

* SCEP Server URL: Example: http://<SCEP Server>/certsrv/mscplmscep.dll for Microsoft Network Device Enrollment Service(NDES)

Challenge: Shared secret for automatic enrollment

Retries: Number of retries when connection fails (0 - 10)

Retry Delay: Duration in seconds between successive retries (0 - 10)

Upload Encryption Certificate: No file chosen Used to encrypt the requests to SCEP Server

Manually upload the encryption certificate or run Test Configuration below with Test Enrollment to upload it automatically.

Current Certificate: Issued To:
Issued By:
Valid:
Details: [Other Certificate Details](#)

☒ Test Connectivity
☐ Test Enrollment

3. Complete the configuration as described below.

Setting	Description
SCEP Server URL	Enter the URL for a SCEP server. The following SCEP servers are supported: Microsoft AD 2008 Symantec mPKI
Challenge	Specify the password required by the SCEP server.
Retries	Specify the number of attempts to access the server when the first attempt fails.
Retry Delay	Specify the number of seconds between retry attempts.
Upload Encryption Certificate	Click Browse to upload the certificate used to encrypt SCEP requests. To upload the certificate automatically, select the Test Enrollment check box, select a CSR template, and click Test Configuration .

4. Click **Save Changes**.

Configuring CSR Templates

If the SCEP server is configured, the Certificate Signing Request (CSR) templates can be used in the VPN, Wi-Fi, and certificate profiles to allow each onboarded device to dynamically obtain certificates for authentication on iOS devices. Up to 10 templates can be defined.

All LDAP attributes (such as **<ldap.userAttrName>**) and variables (such as **<user>**) can be used in the Subject DN, Email, and Subject Alternative Name Value fields. However, if you enter an LDAP variable with a string vector data type in the Subject Alternative Name Value field, only the first value in the string will be used.

To configure CSR templates:

1. In the admin console, choose **Users > Enterprise Onboarding > CSR Templates**.
2. To add a template, click **New CSR Template** or select an existing template that you want to change, duplicate, or delete. Clicking **Duplicate** creates a copy of the selected template with Copy of before the template name.

Enterprise Onboarding > CSR Templates > New Certificate Signing Request Template

New Certificate Signing Request Template

* Name: Label to reference this CSR Template

* Subject DN: Example: CN=<USERNAME>,OU=Employees,O=Company

Email:

Subject Alternative Name Type:

Subject Alternative Name Value:

Key Size: Ensure that the selected Key Size is enabled on the SCEP Server.
An invalid Key Size will cause a certificate request failure.

* indicates required field

3. Specify the following information:

Setting	Description
Name	Specify the template name displayed in the list of CSR templates.
Subject DN	Specify the subject distinguished name. For example: CN=<USERNAME>,OU=Engineering,O=Comp All LDAP attributes (such as <ldap.userAttrName>) and variables (such as <user>) can be used.
Email	(Optional) Specify an email address with the <USER> variable, such as <USER>@sample.net .
Subject Alternative Name Type	Select an alternative name type if the CA requires an alternative subject name. The types include RFC-822 Name (an e-mail address), DNS domain name, URI, and IP address.
Subject Alternative Name Value	Specify one or more values for the selected alternative name type. Multiple values must be separated by a comma or space.  If an LDAP variable is specified that has a string vector data type, only the first value in the string will be used.
Key Size	Select the key size used by the SCEP server.

4. Click **Save Changes**.

Configuring VPN Profiles

VPN profiles provide Android and iOS devices with secure access to enterprise networks. One or more VPN profiles can be assigned to specific user roles or to all roles. Up to 10 profiles can be defined.

All LDAP attributes (such as **<ldap.userAttrName>**) and variables (such as **<user>**) can be used in the Username, Realm, and Role fields.

To define VPN profiles:

1. In the admin console, choose **Users > Enterprise Onboarding > VPN Profiles**.
2. To add a profile, click **New Profile** or select an existing profile that you want to change, duplicate, or delete. Clicking **Duplicate** creates a copy of the selected profile with **Copy of** before the profile name.
3. The first profile that matches a user's role and client type becomes the default VPN profile on the client. Use the arrow keys to move a profile up or down the list.

Enterprise Onboarding > VPN Profiles > New VPN Profile

New VPN Profile

*Name: Label to reference this profile.

Description:

Apply to Client Types: ☒ iOS ☒ Android

*Server URL: Should start with https://.

Role:

Username:

Authentication Method: ☒ Password ☐ Certificate

▼ Roles

Enterprise Onboarding in the Role must be enabled in order for this policy to take effect.

☒ Policy applies to ALL roles

☐ Policy applies to SELECTED roles

☐ Policy applies to all roles OTHER THAN those selected below

Available roles:

Guest

Guest Admin

Users

Selected roles: (none)

4. Specify the following profile information:

Setting	Description
Name	Specify the name to be displayed in the list of VPN profiles.
Description	(Optional) Enter a description of the VPN profile.
Apply to Client Types	Select the device types the profile applies to (Android and iOS only).
Server URL	Specify the URL of the VPN server (must be a IPS device).
Realm	Specify the realm name. The realm is required only if the sign-in URL has the User picks from a list of authentication realms option enabled.
Role	Specify the user role. The user role is required if the role mapping rules for the user realm specify multiple roles and the User must select from among assigned roles option is enabled.
Username	Specify the <USER> variable for the user name.

Setting	Description
Authentication Method	<p>Select Password or Certificate for the user authentication method. For certificate authentication, specify the following:</p> <ul style="list-style-type: none"> • Use CSR Template—Select the CSR template used to obtain the certificate. To create a CSR template, see “Defining CSR Templates”.<XREF> • Enable VPN On Demand—Select this option to allow iOS devices to establish the VPN when a specific host or domain is accessed. To specify the first host or domain: • Match Domain or Host—Enter a hostname or a partial domain name. For example, if you enter example.com, a match occurs when the user accesses any domain that ends with example.com, such as www.test-example.com. • On Demand Action—When a match occurs on the specified host or domain, select whether a VPN is always established, never established, or only if the DNS look-up fails (Establish If Needed). Selecting Never Establish does not prevent an existing VPN from being used. <p>To add another domain, click the + button. To remove a domain, select the check box next to the domain and click the - button. Up to 10 domains can be defined.</p>
Roles	<p>Select one of the following options:</p> <ul style="list-style-type: none"> • Policy applies to ALL roles—To apply this profile to all users. • Policy applies to SELECTED roles—To apply this profile only to users who are mapped to roles in the Selected roles list. Make sure to add roles to this list from the Available roles list. • Policy applies to all roles OTHER THAN those selected below—To apply this profile to all users except for those who map to the roles in the Selected roles list. Make sure to add roles to this list from the Available roles list.

5. Click **Save Changes**.

Configuring Wi-Fi Profiles

Wi-Fi profiles provide Android, iOS, MAC OS X, and Windows devices with secure access to wireless networks. One or more Wi-Fi profiles can be assigned to specific user roles or to all roles. Up to 10 profiles can be defined.

All LDAP attributes (such as **<ldap.userAttrName>**) and variables (such as **<user>**) can be used in the Username and Password fields for the WPA Enterprise and WPA2 Enterprise security types.

To define Wi-Fi profiles:

1. In the admin console, choose **Users > Enterprise Onboarding > WiFi Profiles**.
2. To add a profile, click **New Profile** or select an existing profile that you want to change, duplicate, or delete. Clicking **Duplicate** creates a copy of the selected profile with **Copy of** before the profile name.

Enterprise Onboarding > Wifi Profiles > New Wifi Profile

New Wifi Profile

* Name: Label to reference this profile.

Description:

Apply to Client Types: ☒ iOS ☒ Android ☒ Mac OS X ☒ Windows

* SSID: SSID of the Wifi Network.

Non-Broadcast SSID: ☐

Auto Connect: ☐ Not applicable for Android clients.

Enterprise Onboarding in the Role must be enabled in order for this policy to take effect.

☒ Policy applies to ALL roles

☐ Policy applies to SELECTED roles

☐ Policy applies to all roles OTHER THAN those selected below

Available roles:

Selected roles:

*Indicates required field

3. Specify the following profile information:

Setting	Description
Name	Specify the name to be displayed in the list of Wi-Fi profiles.
Description	(Optional) Enter a description of the profile.
Apply to Client Types	Select the device types the profile applies to (Android, iOS, MAC OS X, and Windows).
SSID	Specify the server set ID of the wireless network.
Non-Broadcast SSID	Select the check box if the wireless network does not broadcast its identity.
Auto Connect	Select the check box to connect the client automatically when the network is detected (not supported by Android clients).

Setting	Description
Security Type	<p>Select the type of authentication used by the network, and specify the password or enterprise settings, as required:</p> <ul style="list-style-type: none">• None—No authentication required.• WEP—Wired Equivalent Privacy used for a non-enterprise network. Enter the network shared key in the displayed text box.• WPA Personal or WPA2 Personal—Wi-Fi Protected Access used for a non-enterprise network. You can select the encryption method (AES or TKIP) and enter the network shared key in the displayed text box (applies to Windows clients only).• WPA Enterprise or WPA2 Enterprise—Wi-Fi Protected Access used for an enterprise network. Select the Extensible Authentication Protocols (EAP) supported by the network's RADIUS authentication server. <p>For Android devices, note the following:</p> <ul style="list-style-type: none">• Android 4.3 or later is required• For the EAP-TLS protocol, the CA certificate must be configured (along with the client certificate) on Samsung devices for authentication.• An 802.1x RADIUS server certificate must be signed by a private root CA. Authentication fails if the certificate is signed by an intermediate root CA.

Setting	Description
EAP	<p>For the WPA Enterprise and WPA2 Enterprise security types, select the supported EAP protocols and specify the associated authentication settings:</p> <ul style="list-style-type: none">• None—If none of the EAP protocols is selected (Android devices only), enter the <USER> and <PASSWORD> variables in the Username and Password fields. <hr/> <p> iOS, MAC OS X, and Windows clients require at least one of the EAP types to be selected (PEAP, EAP-TLS, or EAP-TTLS).</p> <hr/>

Setting	Description
PEAP	<p>The PEAP protocol is supported by all clients. Specify the following:</p> <ul style="list-style-type: none">• Inner Authentication Method—Select the protocol used to authenticate the username and password (None or MSCHAPv2). The None option is valid only for Android devices.• Username and Password—Enter the <USER> and <PASSWORD> variables.• Outer Identity—Specify an alternate username to be used outside the encrypted tunnel, such as anonymous, to conceal the user's identity in unencrypted packets.• Trusted Server Name(s)—Specify the IP address or fully qualified domain name of one or more trusted RADIUS servers used by the network. Multiple servers must be separated by a semicolon.• Trusted CA Certificate—For Windows clients, select the Trusted Root CA of the RADIUS server certificate, even if the device certificate is signed by an intermediate CA. The Trusted Root CA must be configured in a certificate profile before it can be selected here (see "Defining Certificate Profiles")<XREF>. <p>For iOS, MAC OS X, and Android clients, if the RADIUS server certificate is signed by an intermediate CA, create a certificate profile for the intermediate CA, and then select the certificate here. The certificate profile ensures that the intermediate CA is downloaded to the client.</p>

Setting	Description
EAP-TLS	<p>The EAP-TLS protocol is supported by all clients. Specify the following:</p> <ul style="list-style-type: none">• Username—Enter the <USER> variable.• Use CSR Template—Select the CSR template used to obtain the certificate. To create a CSR template, see “Defining CSR Templates”.<XREF>• Trusted Server Name(s)—Specify the IP address or fully qualified domain name of one or more trusted RADIUS servers used by the network. Multiple servers must be separated by a semicolon.• Trusted CA Certificate—For Windows clients, select the Trusted Root CA of the RADIUS server certificate, even if the device certificate is signed by an intermediate CA. The Trusted Root CA must be configured in a certificate profile before it can be selected here (see “Defining Certificate Profiles”)<XREF>. <hr/> <p> On Windows 7 clients that have multiple certificates, users are prompted to select the certificate for 802.1x connections that use EAP-TLS.</p> <hr/> <p>For iOS, MAC OS X, and Android, if the RADIUS server certificate is signed by an intermediate CA, create a certificate profile for the intermediate CA, and then select the certificate here. The certificate profile ensures that the intermediate CA is downloaded to the client.</p>

Setting	Description
EAP-TTLS	<p>The TTLS protocol is supported by all clients. Specify the following:</p> <ul style="list-style-type: none">• Inner Authentication Method—Select the protocol used to authenticate the username and password (None, PAP, or MSCHAPv2). The None option is valid only for Android devices.• Username and Password—Enter the <USER> and <PASSWORD> variables.• Outer Identity—Specify an alternate username to be used outside the encrypted tunnel, such as anonymous, to conceal the user's identity in unencrypted packets.• Trusted Server Name(s)—Specify the IP address or fully qualified domain name of one or more trusted RADIUS servers used by the network. Multiple servers must be separated by a semicolon.• Trusted CA Certificate—For Windows clients, select the Trusted Root CA of the RADIUS server certificate, even if the device certificate is signed by an intermediate CA. The Trusted Root CA must be configured in a certificate profile before it can be selected here (see “Defining Certificate Profiles”)<XREF>. Also, if the RADIUS server certificate is signed by an intermediate CA, then the public intermediate CA must be configured in a certificate profile to ensure that the intermediate CA is downloaded to the client along with the Wi-Fi TTLS profile configuration. <p>For iOS, MAC OS X, and Android clients, if the RADIUS server certificate is signed by an intermediate CA, create a certificate profile for the intermediate CA, and then select the certificate here. The certificate profile ensures that the intermediate CA is downloaded to the client.</p>

Setting	Description
Roles	<p>Select one of the following options:</p> <ul style="list-style-type: none">• Policy applies to ALL roles—To apply this profile to all users.• Policy applies to SELECTED roles—To apply this profile only to users who are mapped to roles in the Selected roles list. Make sure to add roles to this list from the Available roles list.• Policy applies to all roles OTHER THAN those selected below—To apply this profile to all users except for those who map to the roles in the Selected roles list. Make sure to add roles to this list from the Available roles list.

4. Click **Save Changes**.

Configuring Certificate Profiles

Certificate profiles specify the device certificates sent to each client device during onboarding. Up to 10 profiles can be defined.

For security reasons, certificate profiles cannot be included in the XML export or import.

To define certificate profiles:

1. In the admin console, choose **Users > Enterprise Onboarding > Certificate Profiles**.
2. To add a profile, click **New Profile** or select an existing profile that you want to change, duplicate, or delete. Clicking **Duplicate** creates a copy of the selected profile with Copy of before the profile name.

Enterprise Onboarding > Certificate Profiles > New Certificate Profile

New Certificate Profile

* Name: Label to reference this profile.

3. Specify the following information:

Setting	Description
Client Types	Select the device types the profile applies to (Android, iOS, MAC OS X, and Windows).
Import and Use Global Certificate	Select this option to use the IPS global certificate to authenticate the client device. Click Import Certificate & Key , click Browse to locate the certificate file, and then click Import. For more information about device certificates, see "Using Device Certificates".
Import and Use CA Certificate	Select this option to import any CA certificate (public Root CA, private Root, public intermediate CA, or private intermediate CA). These CA's can be used in Wi-Fi profiles and must be downloaded to the client devices. Click Import and Use CA Certificate , click Browse to locate the certificate, and then click Import CA Certificate .
Generate per User Certificate	Select this option to use the SCEP server and a CSR template to generate a certificate for each client. Select a CSR template from the Use Certificate Template list. To create a CSR template, see "Defining CSR Templates" <XREF>.
Roles	Select one of the following options: <ul style="list-style-type: none"> • Policy applies to ALL roles—To apply this profile to all users. • Policy applies to SELECTED roles—To apply this profile only to users who are mapped to roles in the Selected roles list. Make sure to add roles to this list from the Available roles list. • Policy applies to all roles OTHER THAN those selected below—To apply this profile to all users except for those who map to the roles in the Selected roles list. Make sure to add roles to this list from the Available roles list.

4. Click **Save Changes**.

Viewing Onboarded Devices

The Device Management page lists the following types of devices:

Onboarded devices— Devices that have Enterprise Onboarding enabled in the user's role and have been onboarded during device registration. After a device is onboarded, it is displayed on the Device Management page until it is deleted.

The username, user roles, operating system, and registration date are shown for each device, along with the onboarded, and access status. Devices that become inactive or invalid must be deleted manually.

To view the Device Management page:

1. Select **System > Status > Devices**.
2. Use the controls described in table to view and manage the devices in the Device Management page.

Buttons	Administrative Actions	
Update	To view a specific user, enter the username in the Show Users Named box and click Update. If you do not know the exact username, use an asterisk (*) as a wildcard character. To change the number of displayed devices, enter a number in the Show N devices box and click Update. To change the sort, click a column header.	To refresh the page, click Update.
Delete	To delete one or more devices, select the check box next to the appropriate devices and click Delete . If an onboarded device is deleted in error, the user must re-onboard the device. ActiveSync-only devices that are deleted in error are added automatically by the next ActiveSync.	

Buttons	Administrative Actions	
Delete All	To delete the all devices, click Delete All .	

Troubleshooting

You can use the following message IDs in the user access log for troubleshooting:

- AUT31186—Indicates the status of an onboarding attempt (failed or successful)
- AUT31152—Indicates onboarding failed because the maximum device limit of 10000 has been reached
- AUT31187—Indicates the attempt to build a configuration profile failed due to an error
- AUT31188—Indicates a configuration profile was generated successfully, and lists the names of the profiles contained in the configuration profile

The following message IDs are related to device limits:

- SYS31177—Indicates the number of devices onboarded is nearing the system limit of 10000.
- SYS31178—Indicates the number of devices onboarded has exceeded the system limit of 10000 (critical error)
- SYS31193—Information message generated by a background process that attempts to delete device records when 95% of system limit (10000) is reached. It displays the number of device records deleted, the current number of onboarded devices, and the system limit.

If profile generation in the server is successful, but it fails in the client while installing, then the client logs should be analysed for the failure.

Clustering

Overview

A Ivanti Policy Secure(IPS) cluster is a group of IPS devices that act like a single IPS device, which enables high availability, load balancing and parallel processing. A IPS cluster pair is used to refer to a cluster of two IPS devices and a multiunit IPS cluster refers to a cluster of more than two IPS devices.

Clustering provides the following benefits:

- Load balancing- It refers to efficiently distributing the incoming request across a group of IPS devices. It optimizes resource usage, maximizes throughput, minimizes response time, and avoids overload of any single device.
- High Availability (HA)- It provides increased availability and enables uninterrupted access to data even if one of the devices fails.

Deployments

Ivanti Policy Secure(IPS) supports two types of cluster deployments:

- Deployment of Active/Active Cluster
- Deployment of Active/Passive Cluster

Requirements and Limitations

The following are the requirements and limitations for clustering:

- Cluster members must run the same software version.
- Cluster members must use the same hardware platform.
- State synchronization must occur only through the internal Network Interface Card (NIC). Ensure the cluster communication and resource access must take place over an internal network.
- You can deploy active/active or active/passive clustering only within the same IP subnet.

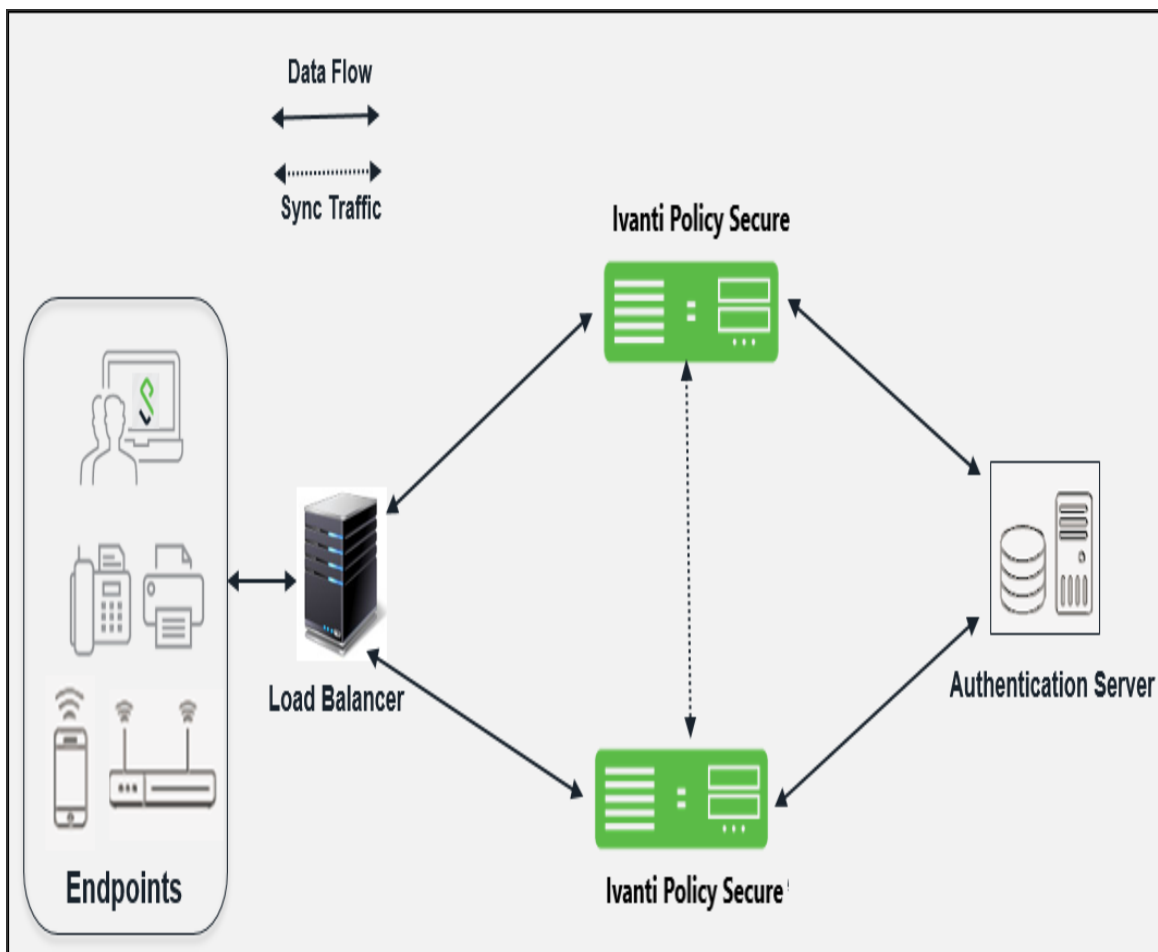

Deployment of Active/Active Cluster

An Active/Active deployment provides load balancing and high availability. IPS relies on an external load balancer for distributing the load among IPS nodes. Active/Active cluster configuration allows increased aggregate system throughput; however, it does not provide increased scalability beyond the total licensed users. It also provides seamless failover, which is achieved by state synchronization between the devices.

If a node goes offline, the load balancer adjusts the load on the active nodes. Users do not need to sign in again, however some session information entered a few seconds before the active machine went offline, such as cookies and passwords, may not have been synchronized on the current device, in which case users may need to sign in again.

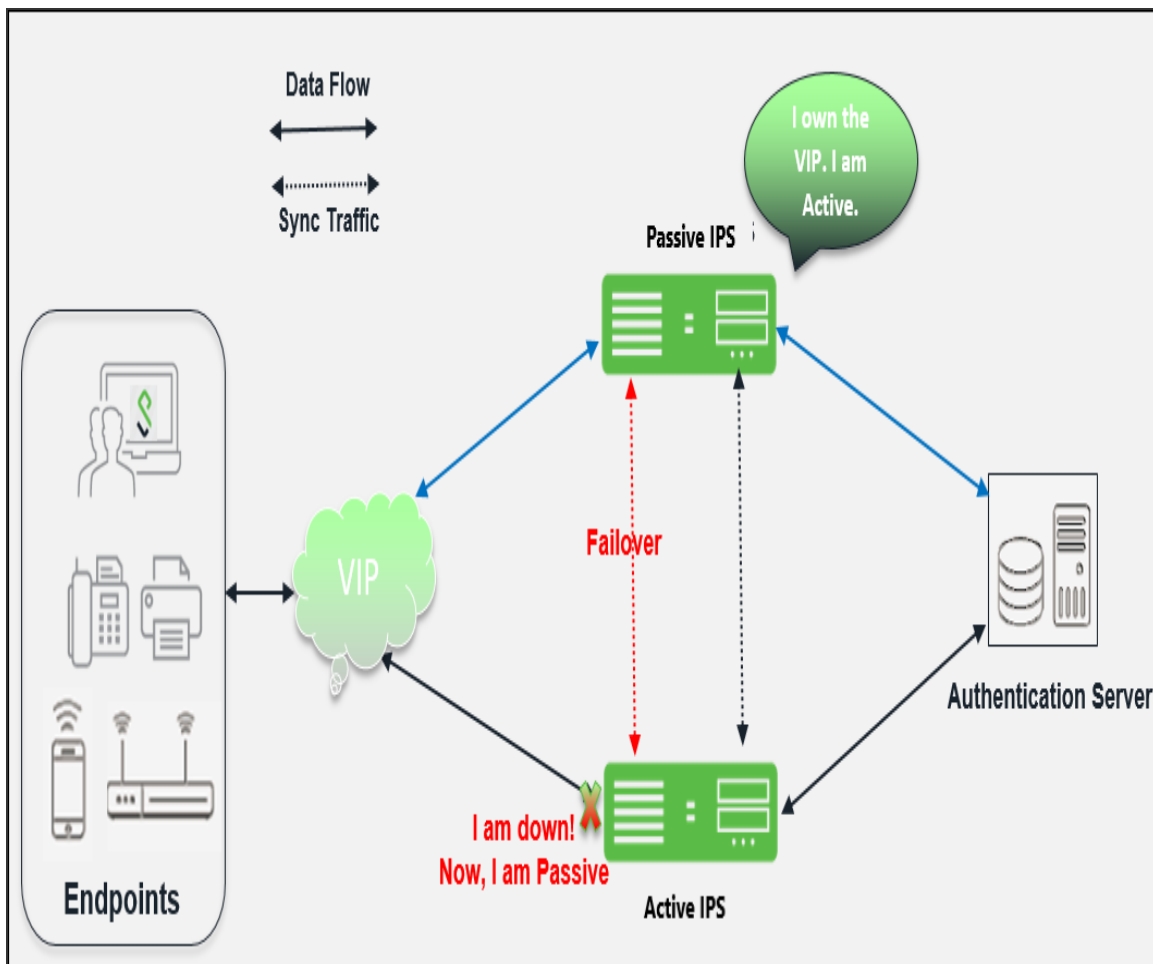

- WAN clustering is not supported.
- Only 2 node A/A Cluster is qualified with IPS.

Deployment of Active/Passive Cluster

An active/passive cluster configuration provides high availability. Active/Passive deployment allows seamless failover without the need to set up any external equipment. The states are synchronized between the two devices for all the configurations so that the devices are virtually identical.

Active/Passive clustering is supported only if the members of the cluster pair are in the same subnet because the VIP address must be shared by both the members. IPS uses a virtual IP (VIP) address to address the cluster pair in addition to addressing each device. The IP address takeover (IPAT) approach is used for the VIP address. If the active node fails, the passive node takes over the VIP address and sends a gratuitous Address Resolution Protocol (ARP) message notifying other networking devices that it now owns the VIP address. You should check that other devices in your network, especially the next-hop gateways, will consider the gratuitous ARP messages.

Cluster Configuration

Admin UI Configuration

Creating a Cluster

To create a cluster:

1. Select **System > Clustering > Create Cluster**.

Clustering > Create New Cluster

Create New Cluster

Join **Create**

Type:

Cluster Name: Name of the cluster to create.
Must be alphanumeric, "-", or "_"; must start with a letter and have a maximum of 19 characters.

Cluster Password: Shared secret among the nodes in the cluster.
Must be at least 6 characters long

Confirm Password: Shared secret among the nodes in the cluster.
Must match the password you typed in the previous line

Member Name: Name of this node in the cluster
Must be alphanumeric, "-", or "_"; must start with a letter and have a maximum of 19 characters.

Create Cluster

Settings	Actions
Cluster Name	Specifies a name to identify the cluster.
Cluster Password	Specifies the cluster password. You need to enter the password again when specifying additional nodes to join the cluster. All nodes in the cluster use this password to communicate.
Confirm Password	Specifies the password that is confirmed.
Member Name	Specifies the name of this node in the cluster.

- Click Create Cluster. When prompted to confirm the cluster creation, click Create. After the device initializes the cluster, the Clustering page displays the Status and Properties tabs.

Cluster Status

Status Properties

Cluster Name: test

Type:

Configuration: Active/Active

Cluster GUID: 69D68A31-9950-8A47-8E6C-71D4105BD46C

Add Members... Enable Disable Remove

10 records per page Search:

		Member Name	Internal Address	External Address	Status	Notes	Sync Rank	Update
	*	node1	10.0.0.1	10.0.0.1	●	Leader	0	

Configuring an Active/Active or Active/Passive Cluster

Once the cluster is created, you can modify the cluster properties to configure the cluster as an Active/Passive cluster. The cluster is created as an Active/Active cluster by default.

i If IPv6 is required, then configure both the nodes with IPv6 settings before creating the cluster.

To configure the cluster properties:

1. Click Properties tab of the cluster.

Clustering > Cluster Properties

Cluster Properties

Status **Properties**

Type:

Cluster Name:

Cluster Password:

Confirm Password:

▼ Configuration Settings

☐ Active/Passive configuration

This is a high-availability failover mode, in which one node is active while the other is held as backup.

Internal VIP:

IPv4: IPv6:

External VIP:

IPv4: IPv6:

☒ Active/Active configuration

▼ Synchronization Settings

☐ Synchronize log messages

☒ Synchronize last access time for user sessions

▼ Network Healthcheck Settings

Number of ARP Ping failures before interface is disabled (should be greater than 0):

☐ Disable external interface when internal interface fails

▼ Advanced Settings

☐ Enable Advanced Settings

2. Complete the configuration as described in the following table. Active/Active configuration is selected by default.

Settings	Actions
Cluster Name	Identifies the cluster.
Configuration Settings	
Active/Passive configuration	Runs a cluster pair in active/passive mode. Then specify an internal VIP (virtual IP address) and an external VIP if the external port is enabled.
Active/Active configuration	(Default) Runs a cluster pair in active/active mode. This configuration runs a cluster of two or more nodes in active/active mode using an external load balancer. To change a two-unit active/passive cluster to an active/active cluster with more than two nodes, first change the configuration of the two-unit cluster to active/active and then add the additional nodes.
Synchronization Settings	
Synchronize log messages	Propagates all log messages among the devices in the cluster.
Synchronize last access time for user sessions	Propagates the latest user access information across the cluster.

Settings	Actions
<div>  <p>- If your cluster node configurations diverge because of changes made to one node while another is disabled or unavailable, the system manages the remerging of the configurations automatically for up to 16 updates. Beyond the maximum number of allowable updates, you might need to intervene and remerge the configurations manually. In some instances, the system might be unable to remerge the configurations if there is not enough overlapping configuration information between two nodes to manage the internode communication.</p> <p>- For example, for a two-node cluster in which the two nodes are partitioned from each other because of a network outage, if the internal network IP address of one of the nodes changes in one of the partitions, the two partitions are unable to rejoin, even when the network is repaired. In such a case, you must remerge the configurations manually.</p> </div> <p>If you configure your cluster as active/passive, synchronize last access time for user sessions option is automatically selected.</p>	
Network Health Check Settings	
Number of ARP Ping Failures	Specifies the number of ARP ping failures allowed before the internal interface is disabled.
Disable external interface when internal interface fails	Disables the external interface of the device if the internal interface fails.
Advanced Settings	
	Specifies the timeouts for the underlying cluster system. Do not change any values under this setting unless instructed to do so by Ivanti Global Support Center.

- Click **Save Changes**.

Adding Cluster Members

To add multiple nodes to a cluster:

1. Select **System > Clustering > Cluster status**.
2. Click **Add Members** Enter the node name and internal IP address.
3. Modify or add the default internal netmask and internal gateway addresses, if necessary.
4. Click **Add**.

Clustering > Cluster Add

Cluster Add

Cluster: test

Delete

	Node Name	Internal IPv4 address	Internal IPv4 Netmask	Internal IPv4 Gateway	
	<input type="text"/>	<input type="text"/>	255.255.252.0	10.204.88.1	Add

Note: after the changes are saved, you must click "Network" on the left panel to check and ensure the network settings for all new nodes are fully configured prior to their joining. Keep in mind that the entire state currently on the new nodes will be completely overwritten during the joining process.

Save Changes Cancel

5. Repeat the process until you have added all the nodes.
6. Click Save Changes to save the node configurations.

The system automatically enables the added nodes, even if they are unreachable.

- You configure the node-specific settings for the newly added node manually because binary import options are not useful.
- The only recommended binary import option into a cluster is "Import everything except network settings and licenses" from the **Maintenance > Import/Export > Configuration** page, which restores cluster-wide configuration (sign-in, realms, roles, resource policies etc.) from a backup binary file. As this option skips node-specific settings, you must perform step 2 manually to populate the newly joined node with the right set of node-specific settings.

License Server

If a license server needs to be configured on both the nodes of a cluster, then perform the following steps:

1. Select **Configuration > Licensing > Configure Server**.
2. Select the setting for **Entire** cluster.
3. Configure the License server IP and preferred network.
4. Click **Save Changes**.

Joining a Node to an Existing Cluster

The following procedure describes how to join a node to the existing cluster.

To join additional nodes to the cluster:

1. From an existing cluster member, select the **System > Clustering > Cluster Status** tab and specify the node you want to add to the cluster.
2. Select the **System > Clustering > Join** tab and enter the following information:
 - The name of the cluster to join
 - The cluster password you specified when defining the cluster
 - The IP address of an active cluster member
3. Click **Join Cluster**. When prompted to confirm joining the cluster, click **Join**.

The join cluster operation validates IPv4 and IPv6 settings for all the physical ports (internal, external, and management) against those present in the existing cluster. For example, the external port IPv6 settings present on Node-Y are compared against external port IPv6 settings that were specified for the Node-Y add member operation entered on the primary node (Node-X). If there is a mismatch, the join operation fails with an appropriate error message.

Clustering > Join Existing Cluster

Join Existing Cluster

Join Create

Cluster Name: Name of the cluster to join

Cluster Password:

Existing Member Address: Internal IP address of any existing cluster member

Join Cluster

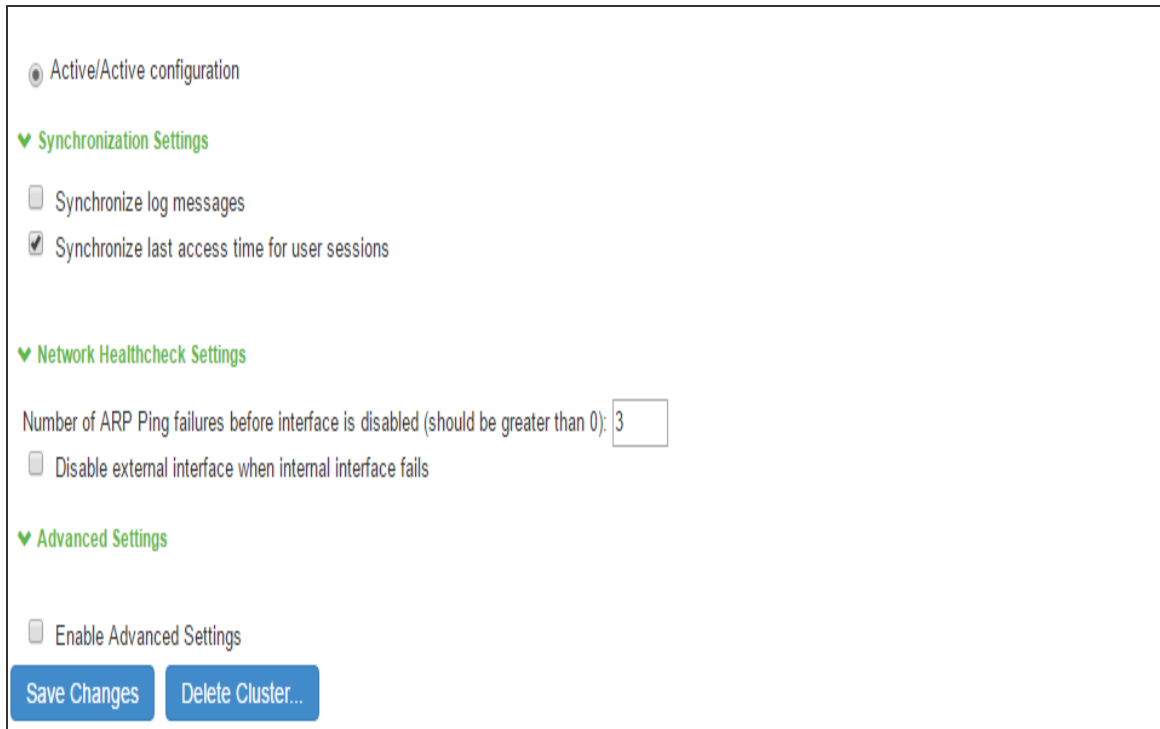

Deleting a Cluster

If you delete a cluster, all the nodes begin running as standalone systems.

To delete a cluster:

1. Select the **System > Clustering > Properties** page.
2. Click **Delete Cluster**.

3. Click **Save Changes**.

The screenshot shows a configuration interface with the following sections and options:

- Active/Active configuration**: A radio button is selected.
- Synchronization Settings**:
 - ☐ Synchronize log messages
 - ☒ Synchronize last access time for user sessions
- Network Healthcheck Settings**:
 - Number of ARP Ping failures before interface is disabled (should be greater than 0):
 - ☐ Disable external interface when internal interface fails
- Advanced Settings**:
 - ☐ Enable Advanced Settings

At the bottom, there are two buttons: **Save Changes** and **Delete Cluster...**

Verifying the Cluster Status

You can verify the cluster status on any node using System > Clustering > Cluster Status page. The list displays each node in the cluster along with its status. In an Active/Passive cluster, you can verify which node owns the VIP and you can force a manual fail over to the passive node by selecting the Fail-over VIP option.

Clustering > Cluster Status

Cluster Status

Status Properties

Cluster Name: test123

	Member Name	Internal Address	External Address	Status	Notes	Sync Rank	Update
	* node1	10.204.54.64/20			Leader	<input type="text" value="0"/>	
	node2	10.204.63.250/20			Enabled, Unreachable	<input type="text" value="0"/>	

GUI Element	Description
Status Information labels	Displays the cluster name, type, configuration, internal VIP, and external VIP for an active/passive cluster.
Add Members button	Click this button to specify a node you intend to add to the cluster. You can add multiple nodes at the same time.
Enable button	Click this button to add a node that was previously disabled. When you add a node, all state information is synchronized on the node.
Disable button	Click this button to disable a node within the cluster. The node retains awareness of the cluster but does not participate in state synchronizations or receive user requests unless members sign in to the node, directly.
Remove button	Click this button to remove the selected node or nodes from the cluster. After removal, the node runs in standalone mode.

GUI Element	Description
Fail-Over VIP	Click this button to failover the VIP to the other node in the active/passive cluster. Only available if cluster is configured as active/passive.
Member Name column	Lists all nodes belonging to the cluster. You can click on a node's name to modify its name and network settings.
Internal Address column	Shows the internal IP address of the cluster member using Classless Interdomain Routing (CIDR) notation.
External Address column	Shows the external IP address of the cluster member using CIDR notation. Note that this column shows only the external IP address of the cluster leader unless you specify a different address for the node on its individual network settings page, which is accessible by clicking its name in the Member Name column. If you change the external IP address on the Network > Network Settings page, the change affects all cluster nodes.
Status column	<p>Shows the current state of the node:</p> <p>Green light, Leader—The node is the active member of an active/active cluster and is handling user requests.</p> <p>Green light/enabled—The node is handling user requests and participating in cluster synchronization.</p> <p>Yellow light/transitioning—The node is joining the cluster.</p> <p>Red light/disabled—The node is not handling user requests or participating in cluster synchronization.</p> <p>Red light/enabled, unreachable —The node is enabled but because of a network issue, it cannot be reached.</p> <p>A node's state is considered standalone when it is deployed outside of a cluster or after being removed from a cluster.</p>
Notes column	<p>Shows the status of the node's connection to the cluster:</p> <p>OK—The node is actively participating in the cluster.</p> <p>ransitioning—The node is switching from the standalone state to the enabled state.</p>

GUI Element	Description
	Unreachable—The node is not aware of the cluster. A cluster member might be unreachable even when it's online and can be pinged. Possible reasons include: its password is incorrect, it doesn't have information about all cluster nodes, it's configured with a different group communication mode, it is running a different service package version, or the machine is turned off.
Sync Rank column	Specifies the synchronization order for nodes when a node rejoins a cluster. Accepts sync ranks from 0 (lowest rank) to 255 (highest rank). The highest rank takes precedence. If two nodes have identical sync ranks, the alphanumeric rank of the member name is used to determine precedence.
Update button	Updates the sync rank after you change the precedence of the nodes in the Sync Rank column.

Load Balancer for Active/Active Cluster

In active/active mode, you have the option of using an external load balancer with a cluster. The load balancer hosts the cluster VIP and routes user requests to a node defined in its cluster group based on source-IP routing. If a node goes off line, the load balancer adjusts the load on the active nodes. Users do not need to sign in again.

The following are the recommendations while choosing and configuring a load balancer for your cluster:

- Listens to traffic on multiple ports
- Manages traffic using assigned source and destination IP addresses (not destination port)

To add a load balancer using an active/active configuration:

1. Select **System > Network > Load Balancer**.

The screenshot shows the 'Load Balancer' configuration page within the 'Network Settings' section. The breadcrumb trail at the top is 'Network > Load Balancer'. Below the breadcrumb, the page title is 'Load Balancer'. A sub-header 'Network Settings' is followed by a 'Load Balancer' link. A horizontal tab bar contains 'Overview', 'Internal Port', 'External Port', 'VLANs', 'Routes', 'Hosts', and 'Load Balancer' (which is highlighted in green). Below the tabs, a message states: 'Enter the load balancer settings and click the Save Changes button at the bottom of the page.' A section titled 'Load Balancer IP Address' with a green heart icon contains the instruction: 'Enter the IP addresses used to access the internal and external interfaces of the Pulse Policy Secure.' This section includes four input fields: 'Internal IPv4 Address', 'External IPv4 Address', 'Internal IPv6 Address', and 'External IPv6 Address'. Below this, a section titled 'Load Balancer Usage' with a green heart icon contains the instruction: 'Use the checkboxes to specify how the load balancer is used.' It features two checkboxes: 'Between endpoints and the Pulse Policy Secure' and 'Between Infranet Enforcers and the Pulse Policy Secure (This option is not supported for IPv6 Addresses)'. At the bottom left is a blue 'Save Changes' button.

2. Enter the IPv4/IPv6 address of the interface connected to the load balancer in the appropriate port window. Do not enter addresses in both fields unless the load balancer is connected to both interfaces.
3. Select the appropriate load balancer usage options.
 - Between endpoints and IPS
 - Between Infranet Enforcers and IPS
4. Click **Save Changes**.

Health Checking a Server from Load Balancer

The system hosts an HTML page that provides service status for each node in a cluster. External load balancers can check this resource to determine how to effectively distribute the load among all the cluster nodes.

To perform the Layer 7 health check for a node:

Using a web browser browser, enter the URL: `https://<IPS Series device-Hostname>/dana-na/healthcheck/healthcheck.cgi?status=all`

This returns either HTTP Status 200 OK or 500 Internal Error. If this returns HTTP Status 200 OK, the following additional parameters are shown.

Parameter Name	Value	Description
CPU-UTILIZATION	0-100	Specifies the CPU utilization percentage (0-100).
SWAP-UTILIZATION	integer	Specifies the swap utilization percentage of the device (0-100).
DISK-UTILIZATION	integer	Specifies the used disk space percentage (0-100).
USER-COUNT	integer	Specifies the total number of licensed users logged in to the device. This does not include any MAC address users or Radius users.
MAX-LICENSED-USERS-REACHED	boolean	Specifies the maximum number of licensed users reached.
Platform-Limit	integer	Specifies the maximum user limit on ISA hardware.
Maximum-License-Count	integer	Specifies the maximum licenses installed directly on the ISA hardware or licenses fetched from the license server.
Cluster-Name	String	Specifies the name given to the cluster. The name must be unique across the network.

The following example performs the Layer 7 health check from an external load balancer:

```
GET /dana-na/healthcheck/healthcheck.cgi?status=all HTTP/1.1\r\nHost: localhost\r\n\r\n
```

The concept of receive string is used for health check. The receive string is configured on the load balancer is used to decide whether the node is active or inactive. It is a regular expression that checks for a value present in the response. For example, IPS sends a page to the load balancer that has USER-COUNT=25 indicating that the number of active licensed users on that device is 25.

A receive string of USER-COUNT\=([0-9][0-9][1-9]|100); means check if USER-COUNT is between 0 and 100. In this example, 25 is between 0 and 100 and the load balancer marks the device as active and considers it for load balancing.

Health check details:

```
CPU-UTILIZATION=4;  
SWAP-UTILIZATION=0;  
DISK-UTILIZATION=6;  
SSL-CONNECTION-COUNT=4;  
PLATFORM-LIMIT=500;  
MAXIMUM-LICENSED-USER-COUNT=200;  
USER-COUNT=1;  
MAX-LICENSED-USERS-REACHED=NO;  
CLUSTER-NAME=IFMAP;
```

Serial Console Configuration

If you are adding a factory-set device to a cluster, we recommend that you use the serial console, which enables you to join an existing cluster during the initialization process by entering minimal information. When a node joins a cluster, it receives the cluster state settings, which overwrite all settings on a device with an existing configuration and provide new machines with the required preliminary information. You can also use the serial console to disable the node. If the node is in a synchronization state, you cannot access its admin console. Therefore, if you need to upgrade or reboot the node, for example, you must first disable the node from a cluster through its serial console.

Joining a Node to a Cluster

To add a node to a cluster through its serial console:

1. Connect to the serial console of the device you want to add to the cluster.
2. Reboot the device and watch its serial console. After the system software starts, a message appears stating that the device is about to boot as a standalone node and to press the Tab key for clustering options. Press the Tab key as soon as you see this option.

The interval to press the Tab key is five seconds. If the device begins to boot in standalone mode, wait for it to finish and then reboot again.

3. Enter 2 to join an existing cluster.
4. Enter the requested information, including:
 - The internal IP address of an active member in the cluster
 - The cluster password, which is the password you entered when defining the cluster
 - The name of the device to add
 - The internal IP address of the device to add
 - The netmask of the device to add
 - The gateway of the device to add
5. The active cluster member verifies the cluster password and that the new device's name and IP address match what you specified in the admin console. If the credentials are valid, the active member copies all its state data to the new cluster member, including certificate, user, and system data.

From the Admin Console, select System > Clustering > Cluster Status of any active cluster member to confirm that the new member's Status is green, indicating that the node is now an enabled node of the cluster (status is green).

If you add a node running an earlier version service package to a cluster, the node automatically detects the mismatch, gets the newer package from the cluster, and joins the cluster.

Disabling a Clustered Node

To disable a node within a cluster using its serial console:

1. Connect to the serial console of the device you want to disable within the cluster
2. Enter 4 for the System Operations option.
3. Enter 8 for Disable Node option.
4. Enter y when the serial console prompts you to confirm that you want to disable the node.
5. From the Admin console, verify that the node has been disabled (status is red) within the cluster by selecting **System > Clustering > Status** of any active cluster member.

Restarting or Rebooting Cluster Nodes Using Its Serial Console

When you create a cluster of two or more nodes, the clustered nodes act as a logical entity. When you reboot one of the nodes using either the serial console or the admin console, all nodes in the cluster restart or reboot.

To reboot only one node:

1. Connect to the serial console of the device you want to disable within the cluster.
2. Enter 4 for System Operations option.
3. Select **System > Clustering > Status** to disable the node you want to restart or reboot within the cluster.
4. Under system operations select the appropriate menu option 9 <Reboot this device>, 10 <Shutdown this device>, or 11 <Restart Services>.
5. Reboot the node, then enable the node within the cluster again.

WAN Clustering

Overview

A WAN cluster is a group of independent servers/nodes separated by WAN networks working together as a single system to provide load balancing and high scalability for clients and services. WAN cluster works only in active-active cluster operation mode and is qualified on ISA4000-V, ISA6000, ISA6000-V, ISA8000, and ISA8000-V, platforms.

Clustering supports following types of synchronization settings:

- Configuration-only Cluster - Only configuration will be synced across the cluster nodes
- Synchronize user sessions - Configuration and user session information will be synced across the Cluster nodes

WAN cluster only supports Configuration-only Cluster and does not support Synchronize user sessions.

Configuring an Active-Active Configuration-only WAN Cluster

To configure an Active/Active Configuration-only WAN cluster:

1. Configure an Active/Active cluster as mentioned in the ["Configuring an Active/Active or Active/Passive Cluster" on page 1009](#) section.

2. Select **System > Clustering > Cluster Properties** and select **Configuration-only Cluster** as shown in the screen below.

Clustering > Cluster Properties

☒ Enable Advanced Settings

Network Type

WARNING: Changing the network type will result in cluster services being restarted.

Select Network Type: Default

Network type selection: Default, Average latency 10-1000us, Average latency 1-10ms, Average latency 10-60ms, Average latency 60-100ms

A non default network type selection will change the underlying cluster system. Change this value only when you observe repeated cluster partitions that may be related to long network delays or significant load in any of the cluster nodes. If a non default network type is picked, the timeout multiplier will silently get reset to the default value.

Timeout Multiplier: Average latency 60-100ms

Restarting Unresponsive Group Communication Subsystem

Save Changes Delete Cluster...

In an Active/Active WAN cluster, if the networks of all the internal ports of the IPS/Nodes are in different subnets, it is mandatory to add specific static network routes on every IPS/Node to reach every other IPS/Node in the cluster for better cluster communication during IPS/Node failover or downtime.

To add a specific static route on a IPS/Node to reach another IPS/Node in the cluster:

1. Select **System > Network > Routes**.
2. Click **New Route**.

Network > Routes

Routes

Network Settings (for node cluster_1)

Settings for: cluster_1 (this node) [Update](#)

Overview Internal Port External Port Management Port VLANs **Routes** Hosts Load Balancer Proxy Server

View route table for: Internal IPv4 [Update](#)

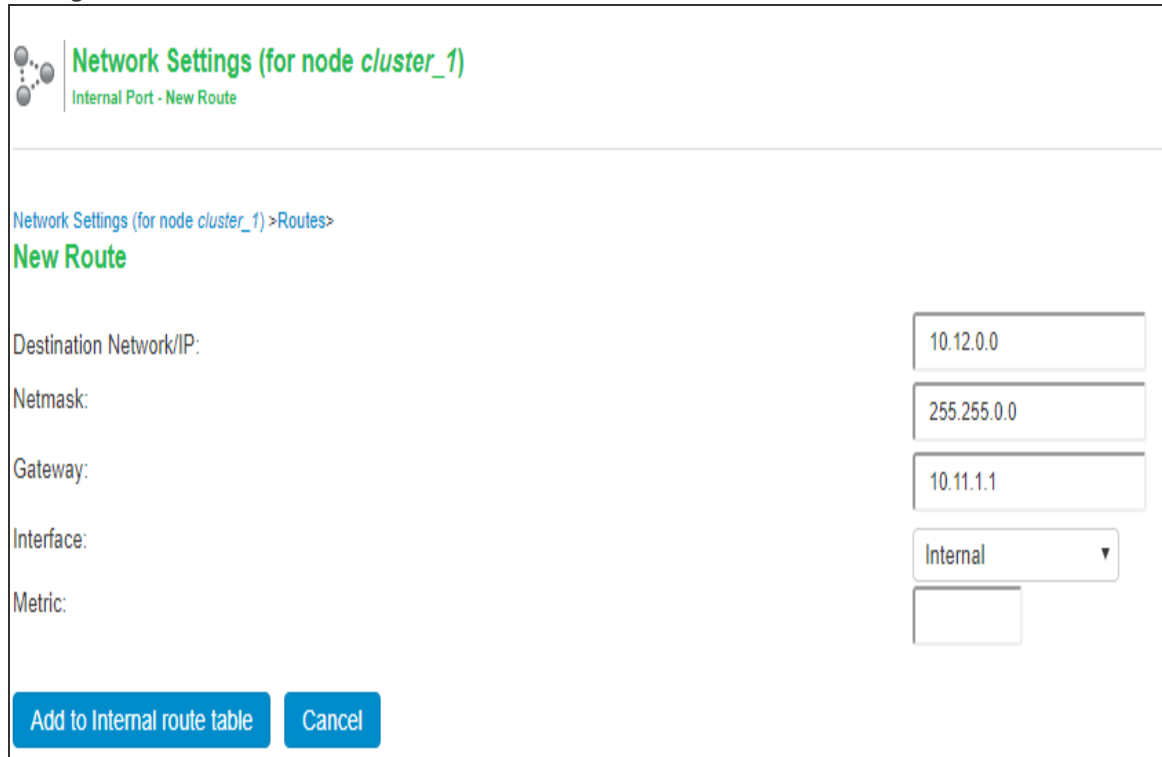

Many networks will not require changes to these routing tables, but if you need to add additional routes, you can do so here.

[New Route...](#) [Delete...](#)

10 records per page Search:

		Internal Port				
	Status	Destination Network/IP	Netmask	Gateway	Interface	Metric (0-15)
default		10.11.0.0	255.255.0.0	0.0.0.0	Internal	0
default		0.0.0.0	0.0.0.0	10.11.1.1	Internal	0

- Based on the Network's Topology the Static Route needs to be added on IPS/Node to reach other IPS/Node in WAN Cluster. Below is an example where static route is added on IPS Configured in 10.11.0.0/16 network having gateway 10.11.1.1 to reach another IPS/Node Configured in 10.12.0.0/16.

The screenshot shows a web interface titled "Network Settings (for node cluster_1)" with a sub-header "Internal Port - New Route". Below this, a breadcrumb trail reads "Network Settings (for node cluster_1) > Routes > New Route". The form contains the following fields:

- Destination Network/IP: 10.12.0.0
- Netmask: 255.255.0.0
- Gateway: 10.11.1.1
- Interface: Internal (selected from a dropdown menu)
- Metric: (empty text box)

At the bottom of the form are two buttons: "Add to Internal route table" and "Cancel".

- The same steps need to be repeated on every IPS/Node in the Active/Active WAN cluster.

Monitoring and Troubleshooting

If you have a problem with a cluster, a representative from Ivanti Global Support Center might ask you to create a snapshot that includes group communication statistics to assist with debugging the cluster problem. When you enable the group communication monitor, the system records statistics related to all the cluster nodes. As the local node communicates with other nodes in the cluster, the system captures statistics related to intra cluster communication. The Group Communication tab is displayed only when you enable clustering on your system. On a standalone system, you do not have access to the Group Communication tab.

You can also enable the cluster networking troubleshooting server on the Network Connectivity page.

- Enabling Monitor all cluster nodes from this node can impact system performance and stability. Perform extensive monitoring ONLY when directed by the Ivanti Support representative.
- Performing log synchronization across cluster nodes can impact your system performance and stability.

Group Communication

To enable group communication monitoring:

- Enter the maximum size of the statistics log.
- Enter the interval, in seconds, at which events are to be logged.

If you want to monitor all cluster nodes from the current local node, select the **Monitor all cluster nodes** from this node check box. If you do not check this option, the group communication monitor gathers statistics only for the local node.

Node monitor under **Maintenance > Troubleshooting > Monitoring > Node Monitor** tab which is enabled by default is NOT related to Monitor all cluster nodes from this node under Group Communication and is not known to cause any system impact.

If you select the Monitor all cluster nodes from this node option, the cluster nodes must be able to communicate over UDP port 6543

1. Select the **Enable group communication monitoring** check box to start the monitoring tool.
2. Click **Save Changes**.

Troubleshooting > Monitoring > Cluster > Group Communication

Group Communication

User Sessions Monitoring Tools System Snapshot Remote Debugging

Debug Log Node Monitor Cluster Diagnostic Logs

Group Communication Network Connectivity

This page allows you to start and stop the group communication monitoring and statistics gathering tool at the local node.

Monitoring is OFF

Maximum statistics log size MBytes 1-5

Monitoring interval Seconds 5-60

Monitor all cluster nodes from this node ☐

Enable group communication monitor ☐

For this option to work correctly, cluster nodes must be able to communicate over UDP port 6543.

Save Changes

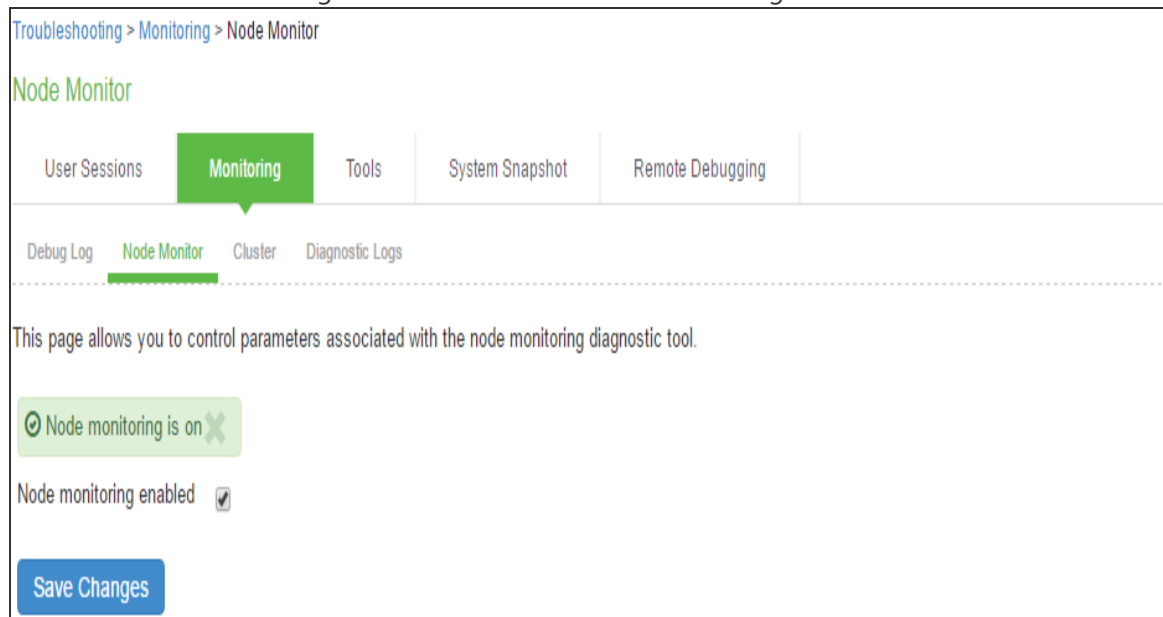

3. If you want to include the node monitoring results in the system snapshot, choose **Maintenance > Troubleshooting > System Snapshot**, and select the Include debug log check box.
4. Take a system snapshot to retrieve the results.

Node Monitoring

To enable node monitoring:

1. Select **Maintenance > Troubleshooting > Monitoring > Node Monitor** to enable the node monitor.
2. Enter the maximum size for the node monitor log.
3. Enter the interval, (in seconds) at which node statistics are to be captured.

4. Select the Node monitoring enabled check box to start monitoring cluster nodes.

5. For Maximum node monitor log size, enter the maximum size (in MB) of the log file. Valid values in the range of 1 - 30.
6. Specify the interval (in seconds) that defines how often nodes are to be monitored.
7. Select the commands to use to monitor the node.
8. If you select dsstatdump, enter its parameters as well.
9. Click **Save Changes**.
10. To include the node monitoring results in the system snapshot, select Maintenance > Troubleshooting > System Snapshot, and select the Include debug log check box.
11. Take a system snapshot to retrieve the results.

Network Connectivity Monitoring

Use the Network Connectivity tab to enable the cluster node troubleshooting server and to select a node on which to perform troubleshooting tasks. The troubleshooting tool allows you to determine the network connectivity between cluster nodes.

The server component of this tool runs on the node to which connectivity is being tested. The client component runs on the node from which connectivity is being tested. The basic scenario for testing connectivity is this:

- The administrator starts the server component on the passive node.
- The administrator tests the connectivity to the server node from the Active node, by starting the client component on the active node and then contacting the passive node running the server component.

The server component must be run on nodes that are configured as either standalone or in a cluster but disabled. Cluster services cannot be running on the same node as the server component.

To enable network connectivity monitoring:

1. Select **Maintenance > Troubleshooting > Cluster > Network Connectivity** and **Enable cluster network troubleshooting server** check box to enable the server component.

The screenshot shows a web interface for network connectivity troubleshooting. The breadcrumb trail is 'Troubleshooting > Monitoring > Cluster > Network Connectivity'. The page title is 'Network Connectivity'. There are four tabs: 'User Sessions', 'Monitoring' (which is selected and highlighted in green), 'Tools', and 'System Snapshot'. Below the tabs, there are four sub-tabs: 'Debug Log', 'Node Monitor', 'Cluster' (which is selected and highlighted in green), and 'Diagnostic Logs'. The main content area has a sub-header 'Group Communication' with 'Network Connectivity' selected. A paragraph explains that the page provides a means of testing network connectivity between nodes. Below this, there is a section titled '▼ Troubleshooting Server'. It contains a checkbox labeled 'Enable cluster network troubleshooting server' which is currently unchecked. Below the checkbox is a text input field labeled 'Client Node:' with a placeholder IP address. To the right of the input field is a small text label: 'IP address or hostname of the client node to troubleshoot (Standalone mode only)'. Below the input field is a blue button labeled 'Save Changes'. Below this is another section titled '▼ Troubleshoot Node'. It contains a dropdown menu labeled 'Select Node:' with 'Standalone Device' selected. To the right of the dropdown is a text input field with a placeholder IP address. To the right of the input field is a blue button labeled 'Go'. A small text label to the right of the input field reads: 'IP address or hostname of the node to troubleshoot'.

2. Click **Save Changes**.
3. On another machine, select **Maintenance > Troubleshooting > Cluster > Network Connectivity**.

Perform one of the following steps:

- Select a node from the list.
 - Enter the IP address of the server node.
4. Click Go to begin troubleshooting the machine on which the server component is running.
 5. Click the Details link below the fields to view the results.

Monitoring using SNMP Traps

You can monitor clusters using the standard logging tools. Specifically, you can use several cluster-specific SNMP traps to monitor events that occur on your cluster nodes, such as:

- External interface down
- Internal interface down
- Disabled node
- Changed virtual IP address (VIP)
- Deleted cluster node (cluster stop)

In general, it is desirable to configure your SNMP traps on a clusterwide basis so that any given cluster node can send its generated traps to the right target. Setting up clusterwide configuration for the traps is particularly important when you also use a load balancer, because you might not know which node is responsible for a specific operation. In that case, the load balancer can independently determine which cluster node can manage an administrative session.

You can use SNMP traps that are included in the Ivanti Standard MIB to monitor these events. These traps include:

- `iveNetExternalInterfaceDownTrap`—Supplies type of event that brought down the external interface.
- `iveNetInternalInterfaceDownTrap`—Supplies type of event that brought down the internal interface.
- `iveClusterDisableNodeTrap`—Supplies the cluster name on which nodes are disabled, along with a space-separated list of disabled node names.
- `iveClusterChangedVIPTrap`—Supplies the type of the VIP, whether external or internal, and its value before and after the change.
- `iveClusterDelete`—Supplies the name of the cluster node on which the cluster delete event was initiated.

These traps are always enabled and available in the MIB. You cannot disable the traps.

Troubleshooting

You can use a built-in feature on the clustering Status page to identify the status of each cluster node. Mouse over the Status light icon to display a tool tip containing a hexadecimal number. The hexadecimal number is a snapshot of the status of the system.

Value	Meaning
0x000001	System is in standalone mode.
0x000002	System is in cluster disabled state.
0x000004	System is in cluster enabled state.
0x000008	System is unreachable (because it is offline, has the wrong password, has a different cluster definition, different version, or other problem).
0x00002000	The node owns the VIPs (on) or not (off).
0x000100	System is synchronizing its state from another node (initial synchronizing phase).
0x000200	System is transitioning from one state to another.
0x00020000	Group communication subsystems at the local and remote nodes are disconnected from each other.
0x00040000	Management interface (mgt0) is displayed disconnected.
0x00080000	Management gateway is unreachable for ARP ping.
0x000800	Interface int0 displays disconnected (no carrier).
0x001000	Interface int1 displays disconnected (no carrier).
0x002000	System is syncing its state to another node that is joining.
0x004000	Initial Synchronization as master or slave is taking place.
0x008000	System is the leader of the cluster.
0x010000	The spread daemon is running and the cache server is connected to it.
0x020000	The gateway on int0 is unreachable for ARP pings (see log file).
0x040000	The gateway on int1 is unreachable for ARP pings (see log file).
0x080000	Leader election is taking place.

Value	Meaning
0x100000	Server lifecycle process is busy.
0x200000	System is performing post state synchronization activities.
0x30004	The spread daemon is running and the cache server is connected to it. The gateway on int0 is unreachable for ARP pings (see log file). System is in cluster enabled state.
0x38004	The spread daemon is running and the cache server is connected to it. The gateway on int0 is unreachable for ARP pings (see log file). System is the leader of the cluster. System is in cluster enabled state.

Each code, as you see it in the system, may relate specifically to one state. However, each code may represent a combination of states, and so the actual code does not appear in the above table. Instead, the code you see in the system is the sum of several of the hexadecimal numbers shown above. You will need to factor out the codes, as in the following example:

- 0x38004—The rightmost digit (4) in this hexadecimal number corresponds to:
 - 0x000004—The system is in a cluster enabled state.
- 0x38004—The digit in the fourth position from the right (8) corresponds to:
 - 0x008000—This system is the leader of the cluster.
- 0x38004—The leftmost digit (3) in this hexadecimal number does not exist in the table, which indicates that it corresponds to the sum of two other digits, in this case, 1 and 2, as shown in the following codes:
 - 0x020000—The gateway on int0 is unreachable for ARP pings (see log file).
 - 0x010000—The spread daemon is running and the cache server is connected to it.

Restarting or Rebooting Cluster Nodes

When you create a cluster of two or more nodes, the clustered nodes act as a logical entity. When you reboot one of the nodes using either the serial console or the admin console, all nodes in the cluster restart or reboot.

To reboot only one node:

1. Select **System > Clustering > Status** to disable the node you want to restart or reboot within the cluster.
2. Select **Maintenance > System > Platform**.
3. Reboot the node, then enable the node within the cluster again.

Appendix

Licensing

Ivanti Policy Secure(IPS) software includes Ivanti Licensing and Software Download Center @ <https://my.pulsesecure.net>, that lets you configure the license server to allow administrators to view all configured systems and move those licenses as needed. Other devices on the network lease licenses from the central license server. For more information, see *License Management Guide*.

Starting with IPS version 5.0, clustering works as follows:

- Clustering does not require a license.
- Place an equal number of licenses on each appliance, when they are joined together to form a cluster, the user licenses add up so that the cluster supports all the licensed users.
- For example, building a 1,000-user cluster is done by bringing together two appliances with 500 user licenses in each of the two units.
- For third-party features, each node in a cluster should have similar license counts.
- The maximum number of concurrent users allowed in a cluster is the sum of all user licenses of all connected nodes.

If your client devices are using IPS prior to release 5.0:

- A license is no longer required to create a cluster. Prior to Release 4.0, to create a multiple node cluster that supports multiple concurrent users, you were required to purchase one ADD-ccccE license for one cluster node, and n-1 CL licenses (one for each of the remaining cluster nodes). For example, to create a 4-node cluster supporting 2000 concurrent users, you needed to purchase one ADD-2000E license and 3 CL licenses.

- CL licenses are no longer necessary but are still supported. When you upgrade to Release 4.0, your existing licenses continue to work. There is no cluster grace period for the node with a CL license installed. When the node with a CL license installed disconnects, the capacity computation is the same as before Release 4.0.
- A 5-day cluster grace period provides license flexibility when a node crashes or loses connectivity with the rest of the cluster.
- We recommend that you distribute your ADD licenses equally across the cluster to avoid losing large number of licenses when a node disconnects from the cluster.

The following table illustrates why we recommend distributing licenses equally across all cluster nodes.

License Distribution	Example
Example 1: Equal distribution	<p>Suppose Node A and Node B are part of a cluster, and each node has 500 concurrent user licenses then the maximum number of licenses is 1000.</p> <p>Suppose Node B disconnects from the cluster. Until the clustering grace period ends, the maximum number of licenses on Node A is 500 (from Node A's original license) + minimum (licenses on Node A (500), licenses on Node B (500)) = 500 + 500 = 1000.</p> <p>After the grace period ends, the maximum number of licenses on Node A reverts to its original license of 500.</p>
Example 2: Unequal distribution	<p>In this example, Node A and Node B are part of a cluster. Node A has 600 ADD licenses and Node B has 400 ADD licenses then the maximum number of licenses is 1000.</p> <p>Suppose Node B disconnects from the cluster. Until the clustering grace period ends, the maximum number of licenses on Node A is 600 (from Node A's original license) + minimum (licenses on Node A (600), licenses on Node B (400)) = 600 + 400 = 1000. After the grace period ends, the maximum number of licenses on Node A is 600.</p> <p>Suppose Node A disconnects from the cluster. Until the clustering grace period ends, the maximum number of licenses on Node B is 400 (from Node B's original license) + minimum (licenses on Node A (600), licenses on Node B (400)) = 400 + 400 = 800. After the grace period ends, the maximum number of licenses on Node B is 400.</p>

License Distribution	Example
Example 3. Unequal distribution (extreme)	<p>In this example, Node A and Node B are part of a cluster. Node A has 1000 ADD licenses and Node B has no ADD licenses.</p> <p>Suppose Node B disconnects from the cluster. Until the clustering grace period ends, the maximum number of licenses on Node A is 1000 (from Node A's original license) + minimum (licenses on Node A (1000), licenses on Node B (0)) = $1000 + 0 = 1000$. After the grace period ends, the maximum number of licenses on Node A is 1000.</p> <p>Suppose Node A disconnects from the cluster. Until the clustering grace period ends, the maximum number of licenses on Node B is 0 (from Node B's original license) + minimum (licenses on Node A (1000), licenses on Node B (0)) = $0 + 0 = 0$. After the grace period ends, the maximum number of licenses on Node B is 0.</p> <p>For the scenarios in Examples 2 and 3, we recommend you distribute the licenses equally amongst the nodes.</p>

Configuring IPv6 on an Existing IPv4 Active/Passive Cluster

We recommend as a best practice that you configure IPv6 host and network settings on individual nodes before you create a cluster. In some cases, such as routine upgrade, you have already created a cluster configuration and only want to add IPv6 addresses to the existing interface configuration. If so, follow the procedures in this section precisely.

You must leave IPv6 disabled until the last step of the procedures shown below.

To modify the internal port configuration for the cluster:

1. Select **System > Network > Internal Port > Settings**.
2. Under **Settings for**, select **Entire cluster**.
3. Complete the configuration for the IPv6 prefix and the IPv6 gateway, but do not enable IPv6.
4. Verify that all the nodes are up and running, are in sync, and are in reachable state. Complete synchronization of the cluster pair might take a few minutes.
5. Under **Settings for**, select **Node 1**.

6. Configure the IPv6 address, but do not enable IPv6.
7. Verify both the nodes are up and running and in reachable state.
8. Repeat steps 6-8 for **Node 2**.
9. Select **System > Network > Internal Port > Virtual Ports**.
10. Update the cluster virtual port configuration to add the IPv6 address.
11. Select **System > Network > Internal Port > Settings**.
12. Under **Settings for**, select **Entire cluster**.
13. Select **Enable IPv6**.

To modify the external port configuration for the cluster:

1. Select **System > Network > External Port > Settings**.
2. Under **Settings for**, select **Entire cluster**.
3. Complete the configuration for the IPv6 prefix and the IPv6 gateway, but do not enable IPv6.
4. Verify that all the nodes are up and running, are in sync, and are in reachable state. Complete synchronization of the cluster pair might take a few minutes.
5. Under **Settings for**, select **Node 1**.
6. Configure the IPv6 address, but do not enable IPv6.
7. Verify both the nodes are up and running and in reachable state.
8. Repeat steps 6-8 for Node 2.
9. Select **System > Network > External Port > Virtual Ports**.
10. Update the cluster virtual port configuration to add the IPv6 address.
11. Select **System > Network > External Port > Settings**.
12. Under **Settings for**, select **Entire cluster**.
13. Select **Enable IPv6**.

Cloud Secure

Cloud Secure provides secure, seamless, and compliant access to cloud resources on a hybrid IT environment where companies are combining the best of the cloud with their own localized data centers. Cloud Secure solution integrates with multiple Ivanti products such as Ivanti Connect Secure, etc.

Cloud Secure provides great level of flexibility with integration to various Third-Party vendors such as MDM vendors, IdP vendors etc. It is a licensed feature, so the Administrator should procure and install the required license.

For more details about the configuration, various deployment scenarios, reports, etc. refer to Cloud Secure documentation available on <https://www.ivanti.com/support/product-documentation>.

For On-Premise deployment usecase, see Configuring IPS for On-Premise users.

For Cloud Application Visibility, see CAV Overview.

System Management

System management includes the following:

- [Network and Host Administration](#)
- [Certificate Security Administration](#)
- [File Management](#)
- [Dashboard and Reports](#)
- [System Maintenance](#)

Network and Host Administration

Network and Host Administration Overview

When you install and initially set up the device, you use the serial port console to set basic network and host settings. To get started, you must use the serial console to configure these settings for the internal interface. You have the option to use the serial console to configure network and host settings for the external interface and the management interface. The network and host settings you configure with the serial port console include:

- IPv4/IPv6 address
- Netmask
- Default gateway
- Speed and duplex
- MTU
- DNS
- Default domain
- WINS

Once the internal interface has been configured, you can use the admin console Network Settings pages to modify settings for the internal interface, to enable and configure the external interface and the management interface, and to configure or manage advanced networking features, including:

- Hostname
- IPv6 addresses
- VLAN ports
- Virtual ports
- Route table entries
- Host mapping table entries
- ARP cache entries

- Neighbor discovery cache entries
- System date and time (manual configuration) or NTP

Configuring the Internal Port

The internal port connects to the local area network (LAN). The internal port settings are configured when you run the setup wizard from the serial console as part of the installation procedure. You can use the System > Network pages to make changes to the configuration.

To modify the internal port configuration:

1. Select **System > Network > Internal Port > Settings** to display the configuration page.
2. Complete the configuration as described in table.
3. Save your changes.

Settings	Guidelines
IPv4 Settings	
IP Address	<p>Assign an IP address. You must assign an IPv4 address to the internal interface. An IP address is an identifier for a computer or device on a TCP/IP network. Networks using the TCP/IP protocol route messages based on the IP address of the destination.</p> <p>The format of an IPv4 address is a 32-bit numeric address written as four numbers separated by periods. Each number can be 0 to 255.</p>
Netmask	<p>Assign a netmask. A netmask indicates which part of an IP address indicates network identification and which part indicates the host identification. For example, the IP address and netmask 10.20.30.1 255.255.255.0 (or 10.20.30.1/24) refer to all the hosts in the 10.20.30.0 subnet. The IP address and netmask 10.20.30.1 255.255.255.255 (or 10.20.30.1/32) refer to a single host.</p>
Default Gateway	<p>Specify the IPv4 address for the default gateway for the routing domain to which the device belongs.</p> <p>A gateway is the router that resides at the point of entry to the current routing domain, often called the default gateway.</p>
IPv6 Settings	
Enable IPv6 / Disable IPv6	<p>Disabled by default. Enable to support access from IPv6 endpoints.</p> <p>When you enable IPv6, the system acquires a link local address.</p> <p>If you switch from enabled to disabled, the system clears the link local address.</p>
Link Local Address	<p>Display the auto configured link local address (after you have enabled and saved the IPv6 configuration).</p>
IPv6 Address	<p>Specify a routable IPv6 address, such as a global unicast address that your network plan has provisioned for this host and interface. Automatic configuration methods are not supported. You must specify the appropriate address manually.</p>
Prefix Length	<p>Specify how many of the higher order contiguous bits of the IPv6 address comprise the prefix (the network portion of the IPv6 address). The default is 64.</p>
Gateway	<p>Specify the IPv6 address for the default gateway for the routing domain to which the device belongs.</p> <p>A gateway is the router that resides at the point of entry to the current routing domain, often called the default gateway.</p>

Settings	Guidelines
Advanced Settings	
MAC Address	Display the MAC address for the interface.
Link Speed	Specify the speed and duplex combination for the interface. If you run SNMP_GET and then change the Link Speed value, you must wait at least 5 minutes after submitting the change before running SNMP_GET again.
ARP Ping Timeout	(IPv4 only) Specify how long the system should wait for responses to Address Resolution Protocol (ARP) requests before timing out. Cluster nodes send ARP requests to the gateways of other nodes to determine if they are properly communicating with one another. If you have not deployed a cluster, the system does not use this setting. If the node belongs to a cluster, the timeout interval that you specify is synchronized across the cluster. In multisite clusters, you can override this setting for the individual nodes in the cluster using options in the System > Clustering page. Use caution when changing this setting in active/passive clusters, however, because the system also uses the ARP Ping Timeout setting on the Internal tab as a failover timer for the VIP.
MTU	Specify the maximum transmission unit. If IPv6 is enabled, the valid range is 1280 to 1500. If IPv6 is not enabled, the valid range is 576 to 1500. We recommend you retain the default MTU setting (1500) unless you must change the setting for troubleshooting purposes.
Default VLAN ID	(Optional) Specify the default VLAN ID for the traffic of this port. When this parameter is set, all the traffic on this interface is subsequently tagged with the set VLAN ID and also accepts only incoming traffic with the same tag. Necessary changes are required on the connected switch port to handle bi-directional tagged traffic.

Settings	Guidelines
	<div> <ul style="list-style-type: none">- If default VLAN ID is set incorrectly or the connected switch port is not configured accordingly, the interface can become unreachable.- Default VLAN ID cannot be set if IPv6 is enabled.- Default VLAN ID is supported in a clustered environment.- In case of VMware ESXi based Virtual Appliance(VA), set the vSwitch configuration to port 4095 to allow IPS to tag the traffic.- The set default VLAN ID should be added as a member in the physical port of switch and the same VLAN should be removed from native VLAN ID.</div>

Configuring the External Port

The external port connects to the Internet. You can use the System > Network pages to configure the external port.

To configure the external port:

1. Select **System > Network > External Port > Settings** to display the configuration page.
2. Complete the configuration as described in table.

3. Save your changes.

Settings	Guidelines
Use Port?	
Use Port?	Select Enabled to use the port; otherwise, select Disabled.
IPv4 Settings	
IP Address	<p>Specify an IP address. An IP address is an identifier for a computer or device on a TCP/IP network. Networks using the TCP/IP protocol route messages based on the IP address of the destination.</p> <p>The format of an IPv4 address is a 32-bit numeric address written as four numbers separated by periods. Each number can be 0 to 255.</p>

Settings	Guidelines
Netmask	Specify a netmask. A netmask indicates which part of an IP address indicates network identification and which part indicates the host identification. For example, the IP address and netmask 10.20.30.1 255.255.255.0 (or 10.20.30.1/24) refer to all the hosts in the 10.20.30.0 subnet. The IP address and netmask 10.20.30.1 255.255.255.255 (or 10.20.30.1/32) refer to a single host.
Default Gateway	Specify the IPv4 address for the default gateway for the routing domain to which the device belongs. A gateway is the router that resides at the point of entry to the current routing domain, often called the default gateway.
IPv6 Settings	
Enable IPv6 / Disable IPv6	Disabled by default. Enable to support access from IPv6 endpoints. When you enable IPv6, the system acquires a link local address. If you switch from enabled to disabled, the system clears the link local address.
Link Local Address	Display the auto configured link local address (after you have enabled and saved the IPv6 configuration).
IPv6 Address	Specify a routable IPv6 address, such as a global unicast address that your network plan has provisioned for this host and interface. Automatic configuration methods are not supported. You must specify the appropriate address manually.
Prefix Length	Specify how many of the higher order contiguous bits of the IPv6 address comprise the prefix (the network portion of the IPv6 address). The default is 64.
Gateway	Specify the IPv6 address for the default gateway for the routing domain to which the device belongs. A gateway is the router that resides at the point of entry to the current routing domain, often called the default gateway.
Advanced Settings	
MAC Address	Display the MAC address for the interface.
Link Speed	Specify the speed and duplex combination for the interface. If you run SNMP_GET and then change the Link Speed value, you must wait at least 5 minutes after submitting the change before running SNMP_GET again.

Settings	Guidelines
ARP Ping Timeout	<p>(IPv4 only.) Specify how long the system should wait for responses to Address Resolution Protocol (ARP) requests before timing out. Cluster nodes send ARP requests to the gateways of other nodes to determine if they are properly communicating with one another.</p> <p>If you have not deployed a cluster, the system does not use this setting. If the node belongs to a cluster, the timeout interval that you specify is synchronized across the cluster. In multisite clusters, you can override this setting for the individual nodes in the cluster using options in the System > Clustering page. Use caution when changing this setting in active/passive clusters, however, because the system also uses the ARP Ping Timeout setting on the Internal tab as a failover timer for the VIP.</p>
MTU	<p>Specify the maximum transmission unit.</p> <p>If IPv6 is enabled, the valid range is 1280 to 1500. If IPv6 is not enabled, the valid range is 576 to 1500.</p> <p>We recommend you retain the default MTU setting (1500) unless you must change the setting for troubleshooting purposes.</p>
Default VLAN ID	<p>(Optional) Specify the default VLAN ID for the traffic of this port. Necessary changes are required on the connected switch port to handle bi-directional tagged traffic.</p> <hr/> <div>  <ul style="list-style-type: none"> - If default VLAN ID is set incorrectly or the connected switch port is not configured accordingly, the interface can become unreachable. - Default VLAN ID cannot be set if IPv6 is enabled. - Default VLAN ID is not supported in a clustered environment. - In case of VMware ESXi based Virtual Appliance(VA), set the vSwitch configuration to port 4095 to allow IPS to tag the traffic. - The set default VLAN ID should be added as a member in the physical port of switch and the same VLAN should be removed from native VLAN ID. </div> <hr/>

JITC Mode Option

To enable the Joint Interoperability Test Command (JITC) mode:

1. Select **System > Configuration > Security > Inbound SSL Options**.
2. Under **DOD certification** option, enable **Turn on JITC** mode.

Configuration > Security > SSL Options

SSL Options

Configuration

Security

Licensing Security Certificates DMI Agent Client Types SAML Guest Access Mobile Client Configuration Advanced Networking Notification

Inbound SSL Options Outbound SSL Options Health Check Options Miscellaneous Advanced

DoD Certification option
When this option is enabled, the web service will be placed in JITC Mode. NDcPP and FIPS Modes will also be turned on and all non-FIPS ciphers will be disabled. The web service will restart.

☒ Turn on JITC mode

SSL NDcPP Mode option
When this option is enabled, the web service will be placed in NDcPP Mode. FIPS Mode will also be turned on and all non-FIPS ciphers will be disabled. The web service will restart. NDcPP Mode is a prerequisite for JITC Mode.

☒ Turn on NDcPP mode

SSL FIPS Mode option
When this option is enabled, the web service will be placed in FIPS Mode, the cipher strength will be set to Medium, and all non-FIPS ciphers will be disabled. The current cipher customization might be lost. The web and RADIUS services will restart. FIPS mode is a prerequisite for NDcPP Mode.

☒ Turn on FIPS mode

NDcPP and FIPS mode are automatically enabled after enabling the **JITC mode**.

3. Click **Save Changes**.

4. With JITC mode enabled, IPS detects any duplicate RADIUS Return and Request Attribute policies and an error message is displayed if the user tries to create a duplicate policy.

Network Access > RADIUS Return Attributes Policies > New Policy

New Policy

Error: Failed to save policy "Ret_policy2". Duplicate policy exist "Ret_policy1"

* Name: Ret_policy2 Required: Label to reference this policy

Description:

Location Group

Specify the Location Group for which this policy applies.

Available Location Groups: Default Guest Cert Auth JITC

Selected Location Groups: (all)

RADIUS Attributes

☒ Open port

☐ VLAN: (1 - 4094)

☐ Return Attribute

Return Attribute	Radius Auth Server Attribute Value	Auth Server Catalog Attribute Value	Value
Filter-Id	-none-	-none-	

With JITC mode enabled, only the first match duplicate RADIUS policy found is reported in the error message.

Important Factors to Consider

Password Strengthening: When JITC is enabled, IPS does not allow an administrator to configure a password exactly same as previously configured 5 passwords. An error message is displayed in this case.

Error: Could not change password. New password must not be one of the previous 5 password(s).

Auth Servers > Administrators > Update Administrator root

Update Administrator root

Full Name:

Authenticate using: Administrators

Password:

Confirm Password:

Start Time:

End Time:

Time Zone: (GMT+05:30) Kolkata, Chennai, Mumbai, New Delhi

☐ One-time use (disable account after the next successful sign-in)
☐ Allow console access
☒ Enabled
☐ Disabled
☐ Quarantined
☐ Require user to change password at next sign in

Note: You must also configure password management on the Authentication server Settings with 'Allow users to change their passwords' option enabled. Use options on the Administrators/Users > Authentication > [Realm] > Authentication Policy > Password page to specify which realms should inherit the server's password management capabilities.

NDcPP Mode Option

NDcPP mode can be enabled in the Inbound tab with a checkbox. This status is also applied over to the Outbound tab. Turning on NDcPP automatically turns on FIPS mode and disables SSL/TLS Version TLS1.0 and below. Also, NDcPP Mode allows to choose only 16 Ciphers under Custom Encryption Strength. Turning on the NDcPP checkbox selects all the NDcPP ciphers by default on both, the Inbound and Outbound sides.

When the NDcPP Mode is enabled, backend server like Windows 2008 R2 which supports the SSL/TLS Version only till TLS1.0 cannot be connected.

syslog-ng server

Connection to syslog-ng server does NOT get established, since syslog-ng does not support TLSv1.1 and TLSv1.2.

rsyslog

Supports only till TLSv1.1. So, connection would not get established, if Outbound SSL Options is set to use TLSv1.2.

- To be NDcPP compliant, NTP Update Interval needs to be limited to 60 minutes. This is to avoid the potential drift becoming too excessive.
- For incoming client certificate during client certificate authentication and for incoming server certificate during backend syslog server connection 1024 bit Key Length is not allowed in both NDcPP and FIPS Mode where as SHA1 Signature Algorithm is not allowed only in FIPS Mode and is allowed in NDcPP Mode. This restriction is not applicable for Outgoing Certificates from IPS during SSL Negotiation.

Inbound Settings

When the NDcPP mode is enabled, the following settings appear by default in the Inbound SSL Options page:

- The Accept only TLS 1.1 and later is enabled by default in the Allowed SSL and TLS Version settings. Only the Accept only TLS 1.1 and Accept only TLS 1.2 options can be chosen. The Accept only TLS 1.0 and later and the Accept SSL V3 and TLS (maximize compatibility) are disabled. See figure
- With regards to the Allowed Encryption Strength settings the Custom SSL Cipher Selection is enabled by default with NDcPP Ciphers. All other options are disabled.

Inbound Settings

Allowed SSL and TLS Version

The older SSL V2 protocol has known security issues addressed by SSL V3 and TLS. It is no longer supported.

- ☒ Accept only TLS 1.2 and later (maximize security)
- ☐ Accept only TLS 1.1 and later
- ☐ Accept only TLS 1.0 and later
- ☐ Accept SSL V3 and TLS (maximize compatibility)

Allowed Encryption Strength

Strong ciphers (rated by the number of bits in the cipher) improve the security of SSL encryption, but some browsers may only support 40-bit ciphers. When there is more than one acceptable cipher, the Pulse Policy Secure will give preference to the cipher with the fastest data transfer rate, regardless of its relative encryption strength. Changing the encryption strength will cause the web service to restart. Please see the Setting Security Options section in the Admin guide for more details.

- ☒ PFS - Perfect Forward Secrecy
- ☐ SuiteB - Accept only SuiteB ciphers (Requires an ECC certificate)
- ☐ Maximize Security (High Ciphers)
- ☐ Maximize Compatibility (Medium Ciphers)
- ☐ Custom SSL Cipher Selection

The following is a list of Selected Ciphers in the Inbound Settings with the NDcPP mode enabled:

- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384

- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384

Outbound Settings

When the NDcPP mode is enabled, the following settings appear by default in the Outbound SSL Options page:

- The Accept only TLS 1.1 and later is enabled by default in the Allowed SSL and TLS Version settings. Only the Accept only TLS 1.1 and Accept only TLS 1.2 are editable. The Accept only TLS 1.0 and later and the Accept SSL V3 and TLS (maximize compatibility) are disabled.
- With regards to the Allowed Encryption Strength settings the Custom SSL Cipher Selection is enabled by default. All other options are disabled.
- Only the NDcPP ciphers configured in the Outbound SSL options settings are sent in the Outbound connections (IPS —> backend SSL).

- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384

Using the Management Port

This topic describes how to configure the management port. It includes the following information:

Management Port Overview

You connect the management port to an Ethernet switch or router that is part of your internal local area network (LAN) and that can connect to your network management infrastructure. When the management port is enabled, the following traffic is directed out the management port: archiving (FTP/SCP), NTP, push config, SNMP, syslog. When the management port is not enabled, that traffic uses the internal port.

Supported Platforms

The following hardware platforms are equipped with a management port: ISA Series

Configuring the Management Port

To configure the management port:

1. Select **System > Network > Management Port > Settings** to display the configuration page.
2. Complete the configuration as described in table.
3. Save your changes.

Network > Management > Management Port - Settings

Management Port - Settings

Network Settings

Settings	Guidelines
Use Port?	
Use Port?	Select Enabled to use the port; otherwise, select Disabled.
IPv4 Settings	
IP Address	<p>Specify an IP address. An IP address is an identifier for a computer or device on a TCP/IP network. Networks using the TCP/IP protocol route messages based on the IP address of the destination.</p> <p>The format of an IPv4 address is a 32-bit numeric address written as four numbers separated by periods. Each number can be 0 to 255.</p>

Settings	Guidelines
Netmask	A netmask indicates which part of an IP address indicates network identification and which part indicates the host identification. For example, the IP address and netmask 10.20.30.1 255.255.255.0 (or 10.20.30.1/24) refer to all the hosts in the 10.20.30.0 subnet. The IP address and netmask 10.20.30.1 255.255.255.255 (or 10.20.30.1/32) refer to a single host.
Default Gateway	Specify the IPv4 address for the default gateway for the routing domain to which the device belongs. A gateway is the router that resides at the point of entry to the current routing domain, often called the default gateway.
IPv6 Settings	
Enable IPv6 / Disable IPv6	Disabled by default. Enable to support network management traffic over IPv6 networks. When you enable IPv6, the system acquires a link local address. If you switch from enabled to disabled, the system clears the link local address.
Link Local Address	Display the auto configured link local address (after you have enabled and saved the IPv6 configuration).
IPv6 Address	Specify a routable IPv6 address, such as a global unicast address that your network plan has provisioned for this host and interface. Automatic configuration methods are not supported. You must specify the appropriate address manually.
Prefix Length	Specify how many of the higher-order contiguous bits of the IPv6 address comprise the prefix (the network portion of the IPv6 address). The default is 64.
Gateway	Specify the IPv6 address for the default gateway for the routing domain to which the device belongs. A gateway is the router that resides at the point of entry to the current routing domain, often called the default gateway.
Advanced Settings	
MAC Address	Display the MAC address for the interface.

Settings	Guidelines
Link Speed	Specify the speed and duplex combination for the interface. If you run SNMP_GET and then change the Link Speed value, you must wait at least 5 minutes after submitting the change before running SNMP_GET again.
ARP Ping Timeout	(IPv4 only.) Specify how long the system should wait for responses to Address Resolution Protocol (ARP) requests before timing out. Cluster nodes send ARP requests to the gateways of other nodes to determine if they are properly communicating with one another. If you have not deployed a cluster, the system does not use this setting. If the node belongs to a cluster, the timeout interval that you specify is synchronized across the cluster. In multisite clusters, you can override this setting for the individual nodes in the cluster using options in the System > Clustering page. Use caution when changing this setting in active/passive clusters, however, because the system also uses the ARP Ping Timeout setting on the Internal tab as a failover timer for the VIP.
MTU	Specify the maximum transmission unit. If IPv6 is enabled, the valid range is 1280 to 1500. If IPv6 is not enabled, the valid range is 576 to 1500. We recommend you retain the default MTU setting (1500) unless you must change the setting for troubleshooting purposes.
Default VLAN ID	(Optional) Specify the default VLAN ID for the traffic of this port. When this parameter is set, all the traffic on this interface is subsequently tagged with the set VLAN ID and also accepts only incoming traffic with the same tag. Necessary changes are required on the connected switch port to handle bi-directional tagged traffic. <hr/> <div> <ul style="list-style-type: none"> - If default VLAN ID is set incorrectly or the connected switch port is not configured accordingly, the interface can become unreachable. - Default VLAN ID cannot be set if IPv6 is enabled. - Default VLAN ID is not supported in a clustered environment. - In case of VMware ESXi based Virtual Appliance(VA), set the vSwitch configuration to port 4095 to allow IPS to tag the traffic. - The set default VLAN ID should be added as a member in the physical port of switch and the same VLAN should be removed from native VLAN ID. </div> <hr/>

Using the Serial Console to Configure the Management Port

To configure management port network settings from the serial console:

1. Start a serial console session.
2. Select item 1, System Settings and Tools.
3. Select item 10, Configure Management port. The text indicates if the option is enabled or disabled.
4. Enter the network settings for the Management Port, as prompted.

If you enable the Management Port but neglect to configure the IP address and netmask, the port reverts to a disabled state. Also, you cannot clear Management Port settings from the serial console when the port is disabled, though you can clear them from within the admin console.

5. When prompted to accept the changes, if they are correct, enter `y`. Otherwise, repeat the process to correct the settings.
6. Close the serial console.

Configuring Administrator Access

You can configure the **Administrators > Admin Realm > Authentication Policy > Source IP restrictions** configuration to enable administrator sign-in through the management port.

You can use Administrator realms to control administrator access to system ports, including the management port.

To control administrator access to the management port:

Enable the management port.

1. Perform one of the following steps:
 - Select **Administrators > Admin Realms > Admin Users** to modify the default admin users realm.
 - Select **Administrators > Admin Realms**, then click **New**, to create a new administrator realm.
2. Select the Authentication Policy > Source IP.
3. Select one of the following options:
 - **Allow users to sign in from any IP address**—Allows users to sign in from any IP address to satisfy the access management requirement.
 - **Allow or deny users from the following IP addresses**—Specifies whether to allow or deny users access from all the listed IP addresses, based on their settings.

To specify access from an IP address:

- Enter the IP address and netmask.
 - Select either Allow to allow users to sign in from the specified IP address, or Deny to prevent users from signing in from the specified IP address.
4. Select the available options to allow administrators to sign in to all available ports, to the management port or the internal port only, or to restrict them from signing in to any of the ports. In some cases, you may inadvertently limit administrative access completely. If this occurs, you can reconfigure the ports by way of the serial console.
 5. Select from the following available options:
 - Enable administrators to sign in on the management port.
 - Enable administrators to sign in on the internal port.
 - Enable administrators to sign in on the external port.

Configuring VLAN Ports

Your network design might include VLANs to provide network segmentation. When connected to a trunk port on a VLAN-enabled switch, the system encounters traffic from all VLANs. This is useful for network designs with separate VLANs for separate classes of users or endpoints, and for making the system accessible from all VLANs. You can use RADIUS attributes to place different users in different network segments.

The system supports IEEE 802.1Q VLAN tagging. You must define a VLAN port for each VLAN. The internal port must be assigned to the root system and must be marked as the default VLAN. Routes to servers reachable from the VLAN interfaces must have the next-hop gateway set to the configured gateway for the VLAN interface, and must have the output port defined as the VLAN port.

When you save the configuration for a new VLAN port, the system creates two static routes by default:

- The default route for the VLAN pointing to the default gateway.
- The interface route to the directly connected network.

To configure a VLAN port:

1. Select **System > Network > VLANs**.
2. Click **New Port** to display the configuration page.
3. Complete the configuration as described in table.
4. Save your changes.

Use Port?	Select Enabled to use the port; otherwise, select Disabled.
VLAN Settings	
Port Name	Specify a name that is unique across all VLAN ports that you define on the system or cluster. Only alphanumeric characters, "-", or "_" are allowed.
VLAN ID	Specify a number between 1 and 4094. The VLAN ID assignment must be unique on the system.
IPv4 Settings	
IP Address	<p>Specify an IP address and netmask combination that is from the same network as the VLAN. VLAN IP addresses must be unique. You cannot configure a VLAN to have the same network as the internal port. For example, if the internal port is 10.64.4.30/16 and you configure a VLAN as 10.64.3.30/16, you might get unpredictable results and errors.</p> <p>The format of an IPv4 address is a 32-bit numeric address written as four numbers separated by periods. Each number can be 0 to 255.</p>
Netmask	Specify a netmask. A netmask indicates which part of an IP address indicates network identification and which part indicates the host identification. For example, the IP address and netmask 10.20.30.1 255.255.255.0 (or 10.20.30.1/24) refer to all the hosts in the 10.20.30.0 subnet. The IP address and netmask 10.20.30.1 255.255.255.255 (or 10.20.30.1/32) refer to a single host.
Default Gateway	<p>Specify the IPv4 address for the default gateway for the routing domain to which the device belongs.</p> <p>A gateway is the router that resides at the point of entry to the current routing domain, often called the default gateway.</p>
IPv6 Settings	
IPv6 settings	Select Enable IPv6 to use the port; otherwise, select Disable IPv6.
IPv6 Address	Specify a routable IPv6 address, such as a global unicast address that your network plan has provisioned for this host and interface. Automatic configuration methods are not supported. You must specify the appropriate address manually.

Settings	Guidelines
Prefix Length	Specify how many of the higher order contiguous bits of the IPv6 address comprise the prefix (the network portion of the IPv6 address). The default is 64.
Default Gateway	Specify the IPv6 address for the default gateway for the routing domain to which the device belongs. A gateway is the router that resides at the point of entry to the current routing domain, often called the default gateway.

- Link speed, ARP ping timeout, and MTU settings are inherited from the internal port configuration.

- To configure an external VLAN port, Select System > Network > VLANs > External Port > New VLAN Port -Settings.

- To configure a Management port, Select System > Network > VLANs > Management Port > New VLAN Port -Settings.

Using Virtual Ports

Configuring Virtual Ports

You can use virtual ports to provide different groups of users access to the same system using different IP aliases and domains.

Virtual ports are associated with the physical internal port and physical external port. The virtual port shares all the network settings with the associated physical port, except for the IP address.

When you configure virtual ports, you are creating name-IP address pairs. The names and IP addresses must be unique in your network. An alias can include IPv4 addresses, IPv6 addresses, or both. However, the corresponding IP protocol must be enabled on the physical port for the addresses to take effect.

To configure a virtual port:

1. Select **System > Network > PortName > Virtual Ports**. PortName is Internal Port or External Port.
2. Click **New Port** to display the configuration page.

3. Complete the configuration as described in table.
4. Save your changes.

Settings	Guidelines
Name	Specify a name for the virtual port. The names and IP addresses in the virtual port configuration must be unique in your network.
Physical Port	Display the name of the physical port associated with the virtual port. The virtual port inherits link speed, ARP ping timeout, and MTU settings from the physical port configuration.
IPv4 Address	Specify an IPv4 address. An alias can include IPv4 addresses, IPv6 addresses, or both. However, the corresponding IP protocol must be enabled on the physical port for the addresses to take effect.
IPv6 Address	Specify an IPv6 address. An alias can include IPv4 addresses, IPv6 addresses, or both. However, the corresponding IP protocol must be enabled on the physical port for the addresses to take effect.

Using Device Certificates with Virtual Ports

Virtual ports can be used to create multiple fully qualified domain names for user sign-in. When a user tries to sign in using the IP address defined in a virtual port, the system presents the certificate associated with the virtual port to initiate the SSL transaction.

You can approach the digital certificate security and virtual ports implementation in either of the following ways:

- **Associate all hostnames with a single certificate**—With this approach, you use a single wildcard certificate to validate the identity of all system hostnames, regardless of which hostname is used to sign in. A wildcard certificate includes a variable element in the domain name, making it possible for users who sign in from multiple hosts to map to the “same” domain. For example, if you create a wildcard certificate for *.yourcompany.com, the system uses the same certificate to validate its identity to users who sign in to employees.yourcompany.com as it does to users who sign into partners.yourcompany.com.
- **Associate each hostname with its own certificate**—With this approach, you associate different hostnames with different certificates. Create a virtual port for each hostname. A virtual port activates an IP alias on a physical port. For example, you can create two virtual ports on a single appliance, mapping the first virtual port to the IP address 10.10.10.1 (sales.yourcompany.com) and the second virtual port to the IP address 10.10.10.2 (partners.yourcompany.com). Then you can associate each of these virtual ports with its own certificate, ensuring that users authenticate through different certificates.

To associate certificates with virtual ports:

1. Create virtual ports.
2. Import the device certificates.
3. Associate the device certificates with the virtual ports:
4. Select **System > Configuration > Certificates > Device Certificates**.
5. Click the link of the device certificate you want to configure to display the configuration page.
6. Use the controls in the “Present certificate on these ports” section to associate ports with the certificate.

Configuring the System Date and Time

You can use the admin console to set the system date and time manually or by configuring a network time protocol (NTP) server. The system supports NTPv4, which is backwards compatible with NTPv3 and NTPv2.

BEST PRACTICE: We recommend you use NTP to synchronize the date and time clocks on all network systems. Using NTP obviates issues that might occur with cluster synchronization, network communication that uses time-sensitive protocols, such as SAML, and implementation of time-based policies, such as local authentication server account expiration. In addition, using NTP as a standard in your network rationalizes timestamps in logs, which facilitates reporting and troubleshooting.

On a VMware virtual appliance, the data may be erased each hour if the same NTP server is not defined on the license server, and on the ESXi server.

To set the system date and time:

1. Select **System** > **Status** > **Overview** to display the System Status dashboard.

2. Click the **System Date and Time Edit** link to display the configuration page.

Status > Overview > Date and Time

Time	Specify the time and select AM or PM.

Configuring NTP and Other Services Traffic Over Any Physical Interface

The NTP, SNMP, Syslog, and Log archiving services are set to send the traffic through Management port by default. In case the Management port is not available, the traffic is routed through Internal port. Now, an administrator can modify the settings of NTP and other services to any physical interface.

The following procedure describes the steps to configure the ports for the services. Before you proceed, ensure the External and Management ports are enabled for use in the network settings.

To configure NTP and other Services:

1. Select **System > Configuration > Advance Networking**.
2. For the individual service, select the required port from the drop-down list.

The screenshot shows a web interface for 'Configuration > Advanced Networking'. The page has a breadcrumb trail 'Configuration > Advanced Networking' and a title 'Advanced Networking'. Below the title is a horizontal menu with tabs: Licensing, Pulse One, Security, Certificates, DMI Agent, Sensors, Client Types, SAML, Guest Access, Advanced Networking (highlighted in green), and Notification. The main content area has a green heading 'Select the source port to be used for the following features'. Below this heading are four rows, each with a label and a dropdown menu: NTP (External), SNMP Traps (Internal), Syslog (Internal), and Log Archiving (Management). At the bottom left of the form is a blue 'Save Changes' button.

In a cluster environment, when a node joins the cluster, configuration of the node is replaced with the configuration of other nodes in the cluster.

Configuring Network Services

You configure DNS and WINS services when you initially configure the system with the serial console. If necessary, you can use the System > Network > Overview page to modify the configuration. You can also use this page to configure a hostname.

The network services overview page also displays the node name (if the node belongs to a cluster), and the status and interface statistics for the internal port, external port, and management port.

To configure network services:

1. Select **System > Network > Overview** to display the configuration page.
2. Complete the configuration as described in table.

3. Save your changes

Controls	Description
View route table for	Use the controls to change the display to show the route table for internal, external, or management interfaces; and for IPv4 or IPv6 routes.
Delete	Select a row in the table and click Delete to delete a route.
New Route	Click New Route and complete the configuration to add a route to the table. You must specify a valid IP address, gateway, DNS address, and metric. The metric is a way of comparing multiple routes to establish precedence. Generally, the lower the number (from 1 to 15), the higher the precedence. Thus, a route with a metric of 2 is chosen over a route with a metric of 14. The metric value of zero (0) identifies the route as one that should not be used.

Managing the Hosts Table

In general, the system uses the configured DNS servers to resolve hostnames, but it also maintains a local hosts table that can be used for name resolution. The system populates some entries from host-IP address pair settings in your configuration. You can add host-IP address mappings for other hosts that might not be known to the DNS servers used by the system, or in cases where DNS is not reachable.

To manage the hosts table:

1. Select **System > Network > Hosts** to display the hosts table.

Network > Hosts

Hosts

Delete	Click the delete icon in the last column to delete the row from the table.

Managing the ARP Table

ARP stands for Address Resolution Protocol. In IPv4 networking, network nodes use ARP to maintain information about peer network nodes. ARP is used to associate the Layer 3 IP address with a Layer 2 MAC address of neighboring peer nodes. The system maintains an ARP table with dynamic, cached entries, and you can add static entries if necessary. The system caches dynamic entries for up to 20 minutes. Dynamic entries are deleted during a reboot. Static entries are restored after a reboot.

To manage the ARP table:

- 1. Select **System > Network > Port > ARP Cache**. Port is the Internal Port, External Port, or Management Port tab.

Network > Internal > Internal Port - ARP Cache

Internal Port - ARP Cache

ND Cache

This shows the current ARP table for this port. These mappings are automatically created, but if necessary, you can add or remove entries.

Delete...

Delete Dynamic Entries

	IP Address	Physical Address	Type	
	<input type="text"/>	<input type="text"/>		<div>Add</div>
	10.204.88.1	00:1F:12:35:64:40	Dynamic	
	10.204.89.92	00:10:DB:FF:10:07	Dynamic	
	10.204.91.254	00:26:88:6E:CE:01	Dynamic	

- 2. Use the controls described in table to manage the ARP table.

Controls	Description
Delete	Select a row in the table and click Delete to delete the entry.
Delete Dynamic Entries	Delete all dynamically discovered entries.
Add	Specify an IP address, a MAC address, and click Add to add an entry. If you add an entry that has the same IP address as an existing entry, the system overwrites the existing entry with your new entry.

Managing the Neighbor Discovery Table

In IPv6 networking, network nodes use the [Neighbor Discovery Protocol \(NDP\)](#) to determine the Layer 2 MAC addresses for neighboring hosts and routers. The system uses NDP to maintain a cache of neighboring routers that are reachable and can forward packets on its behalf.

To manage the neighbor discovery table:

1. Select **System > Network > Port > ND Cache**. **Port** is the Internal Port, External Port, or Management Port tab.

2. Select **Flush NDP Entries** to delete all dynamically discovered entries.

Network > Internal > Internal Port - ND Cache

IPv6 Address	Physical Address	Type	

Using IPv6

This topic describes support for using IPv6.

Understanding IPv6

IP version 6 (IPv6) is an Internet Protocol designed to succeed IP version 4 (IPv4). This topic provides an overview of IPv6.

About IPv6

The ongoing expansive growth of the Internet and the need to provide IP addresses to accommodate it is escalating the emergent use of a new IP protocol. IPv6 was designed to satisfy the current and anticipated near future requirements.

IPv4 is widely used throughout the world today for the Internet, intranets, and private networks. IPv6 builds upon the functionality and structure of IPv4 in many aspects, including:

- Larger address space-IPv6 addresses are 128 bits long instead of 32 bits. This expands the address space from 4 billion addresses to over 300 trillion trillion addresses.
- New datagram format-The packet header is both simplified and enhanced to enable more secure and efficient routing.
- Improved fragmentation and reassembly-The maximum transmission unit (MTU) has been increased to 1280 bytes, for example.
- Transition mechanisms-Various network address translation (NAT) and tunneling mechanisms have been developed to support the transition to IPv6.

On February 3, 2011 Internet Assigned Numbers Authority (IANA) allotted the last block of IPv4 addresses to Regional Internet Registries (RIR), so the free pool of IPv4 addresses is now fully depleted. It is expected that in the near future Internet service providers (ISPs) will start issuing IPv6 addresses to their customers.

About IPv6 Address Types

[RFC 4291, IP Version 6 Addressing Architecture](#) describes the following types of IPv6 addresses:

- Unicast. An identifier for a single interface. A packet sent to a unicast address is delivered to the interface identified by that address.
- Anycast. An identifier for a set of interfaces. A packet sent to an anycast address is delivered to one of the interfaces identified by that address.
- Multicast. An identifier for a set of interfaces. A packet sent to a multicast address is delivered to all interfaces identified by that address.

The link-local address is a special IPv6 unicast address that is used in self-traffic and essential network communication, like Neighbor Discovery Protocol (NDP). When you enable IPv6 on a Connect Secure interface, the system generates a link-local address that is derived from the interface MAC address.

When you configure IPv6 addresses for the system interfaces, you manually specify a routable address, such as global unicast address or an anycast address, depending on your routing implementation and your system deployment. A global unicast address must be globally unique so that it can be specified globally without need for modification. An anycast address represents a service rather than a specific device. An anycast address is not unique, but instead might be configured on each device in a cluster. You are not likely to use multicast addressing with Connect Secure.

About IPv6 Address Text Representation

All IPv6 addresses are 128 bits long, written as 8 sections of 16 bits each. They are expressed in hexadecimal representation, so the sections range from 0 to FFFF. Sections are delimited by colons, and leading zeroes in each section may be omitted. If two or more consecutive sections have all zeroes, they can be collapsed to a double colon.

IPv6 addresses consist of 8 groups of 16-bit hexadecimal values separated by colons (:). IPv6 addresses have the following format:

aaaa:aaaa:aaaa:aaaa:aaaa:aaaa:aaaa:aaaa

Each aaaa is a 16-bit hexadecimal value, and each a is a 4-bit hexadecimal value. The following is a sample IPv6 address:

2001:0DB8:0000:0000:0008:0800:200C:417A

You can omit the leading zeros of each 16-bit group, as follows:

2001:DB8:0:0:8:800:200C:417A

You can compress 16-bit groups of zeros to double colons (::) as shown in the following example, but only once per address:

2001:DB8::8:800:200C:417A

About the IPv6 Unspecified Address

In the IPv6 address space, the special "unspecified address" is 0:0:0:0:0:0:0:0. The compressed representation of the unspecified address is the double-colon (::). The unspecified address must never be assigned to a physical or virtual interface.

About the IPv6 Loopback Address

The special loopback address is the unicast address 0:0:0:0:0:0:0:1. The compressed representation of the loopback address is ::1. The loopback address may be used by a node to send an IPv6 packet to itself. It must not be assigned to a physical or virtual interface.

About IPv6 Address Prefixes

An IPv6 address prefix is a combination of an IPv6 prefix address and a prefix length used to represent a block of address space (or a network), similar to the use of an IPv4 subnet address and netmask combination to specify a subnet. An IPv6 address prefix takes the form ipv6-prefix/prefix-length. The ipv6-prefix variable follows general IPv6 addressing rules. The /prefix-length variable is a decimal value that indicates the number of contiguous, higher-order bits of the address that make up the network portion of the address. For example, 2001:DB8::/32 is an IPv6 address prefix, indicating that the first 32 bits make up the network portion of the address.

System Normalization of IPv6 Addresses

The system validates and normalizes IPv6 addresses entered by administrators. The normalized address is the address processed by the system, and it is the address that appears in logs.

The following table gives examples of how the system normalizes IPv6 address entries.

Example Entry	Normalized Address	Explanation
2001:DB8:1:1::3	2001:DB8:1:1::3	An address specified in compressed format is validated; the system uses the compressed form as the normalized form.
0:0:0::122	::122	Address is validated and normalized to compressed format.

FF01:0:0:0:0:0:101	FF01::101	Address is validated and normalized to compressed format.
2001:DB8::10.204.50.122	2001:DB8::ACC:327A	Address is validated and normalized to hexadecimal representation.
::FFFF:10.204.50.122	::FFFF:10.204.50.122	An address specified in compressed format is validated; the system uses the compressed form as the normalized form.

About Neighbor Discovery Protocol

[Neighbor discovery protocol \(NDP\)](#) allows different nodes on the same link to advertise their existence to their neighbors, and to learn about the existence of their neighbors.

Routers and hosts (nodes) use NDP messages to determine the linklayer addresses of neighbors that reside on attached links and to overwrite invalid cache entries. Hosts also use NDP to find neighboring routers that can forward packets on their behalf.

In addition, nodes use NDP to actively track the ability to reach neighbors. When a router (or the path to a router) fails, nodes actively search for alternatives to reach the destination.

IPv6 NDP corresponds to a number of the IPv4 protocols - ARP, ICMP Router Discovery, and ICMP Redirect. However, NDP provides many improvements over the IPv4 set of protocols. These improvements address the following:

- Router discovery-How a host locates routers residing on an attached link.
- Prefix discovery-How a host discovers address prefixes for destinations residing on an attached link. Nodes use prefixes to distinguish between destinations that reside on an attached link and those destinations that it can reach only through a router.
- Parameter discovery-How a node learns various parameters (link parameters or Internet parameters) that it places in outgoing packets.
- Address resolution-How a node uses only a destination IPv6 address to determine a link-layer address for destinations on an attached link.
- Next-hop determination-The algorithm that a node uses for mapping an IPv6 destination address into a neighbor IPv6 address (either the next router hop or the destination itself) to which it plans to send traffic for the destination.
- Neighbor unreachability detection-How a node determines that it can no longer reach a neighbor.

- Duplicate address detection-How a node determines whether an address is already in use by another node.

A router periodically multicasts a router advertisement from each of its multicast interfaces, announcing its availability. Hosts listen for these advertisements for address autoconfiguration and discovery of link-local addresses of the neighboring routers. When a host starts, it multicasts a router solicitation to ask for immediate advertisements.

The router discovery messages do not constitute a routing protocol. They enable hosts to discover the existence of neighboring routers, but they are not used to determine which router is best to reach a particular destination.

NDP uses the following Internet Control Message Protocol version 6 (ICMPv6) messages: router solicitation, router advertisement, neighbor solicitation, neighbor advertisement, and redirect.

NDP for IPv6 replaces the following IPv4 protocols: Router Discovery (RDISC), Address Resolution Protocol (ARP), and ICMPv4 redirect.

Configuring SSL Options

Use the System > Configuration > Security > SSL Options page to change the default security settings. We recommend that you use the default security settings, which provide maximum security, but you may need to modify these settings if your users cannot use certain browsers or access certain Web pages.

TLS_DHE_RSA_WITH_AES_128_CBC_SHA TLS_DHE_RSA_WITH_AES_256_CBC_SHA cipher suites are supported. Both these ciphers use RSA for server authentication and ephemeral Diffie-Hellman (DHE) for key exchange. RSA server certificate is required for these ciphers. Only TLS_DHE_RSA_WITH_AES_256_CBC_SHA is available with the Accept 168-bit and greater option. In the Custom SSL Cipher configuration, TLS_DHE_RSA_WITH_AES_128_CBC_SHA is available only when AES-Medium is selected and TLS_DHE_RSA_WITH_AES_256_CBC_SHA is available only when AES-High is selected. Both ciphers are lower in priority over the other widely used cipher suites.

FIPS Level 1 Support

Once you enable FIPS level 1 support, your browser is restricted to specific custom cipher strengths. A list of supported ciphers is shown during the enabling process.

When you enable FIPS level 1 support, the following events occur on the system:

- The Web server restarts and turns on FIPS level 1 support. The Web server now allows only TLSv1.0, TLSv1.1 and TLSv1.2 protocols that include FIPS approved cryptographic algorithms which include Suite B cipher suites.

Once FIPS level 1 support is enabled, new client sessions will use FIPS if the client supports FIPS. Existing client sessions may not be using FIPS. To ensure FIPS capable clients are in FIPS level 1 support, all client sessions should be terminated after the FIPS level 1 support is enabled. Administrators can use the **System > Status > Active Users** page to terminate client sessions.

- If the platform features hardware acceleration, when FIPS level 1 support is enabled SSL processing does not utilize the hardware acceleration. IPsec hardware acceleration is not affected.

The following event logs are generated for FIPS level 1 support:

- SYS30966 when the web server turns FIPS level 1 support on.
- ADM30965 when the administrator turns FIPS level 1 support on or off.
- ERR30967 when the web server fails to turn on FIPS level 1 support.

To enable FIPS level 1 support:

1. Select **System > Configuration > Inbound SSL Options**.
2. Under SSL FIPS Mode option, select **Turn on FIPS mode**.

Configuration > Security > SSL Options

SSL Options

Configuration

Security

Licensing Security Certificates DM Agent Client Types SAML Guest Access Mobile Client Configuration Advanced Networking Notification

Inbound SSL Options Outbound SSL Options Health Check Options Miscellaneous Advanced

DoD Certification option
When this option is enabled, the web service will be placed in JITC Mode. NDcPP and FIPS Modes will also be turned on and all non-FIPS ciphers will be disabled. The web service will restart.

☒ Turn on JITC mode

SSL NDcPP Mode option
When this option is enabled, the web service will be placed in NDcPP Mode. FIPS Mode will also be turned on and all non-FIPS ciphers will be disabled. The web service will restart. NDcPP Mode is a prerequisite for JITC Mode.

☒ Turn on NDcPP mode

SSL FIPS Mode option
When this option is enabled, the web service will be placed in FIPS Mode, the cipher strength will be set to Medium, and all non-FIPS ciphers will be disabled. The current cipher customization might be lost. The web and RADIUS services will restart. FIPS mode is a prerequisite for NDcPP Mode.

☒ Turn on FIPS mode

Inbound Settings

Allowed Encryption Strength
Strong ciphers (rated by the number of bits in the cipher) improve the security of SSL encryption, but some browsers may only support 40-bit ciphers. When there is more than one acceptable cipher, the Ivanti Policy Secure will give preference to the cipher with the fastest data transfer rate, regardless of its relative encryption strength. Changing the encryption strength will cause the web service to restart. Please see the Setting Security Options section in the Admin guide for more details.

☐ PFS - Perfect Forward Secrecy
☐ SuiteB - Accept only SuiteB ciphers (Requires an ECC certificate)
☐ Maximize Security (High Ciphers)
☐ Maximize Compatibility (Medium Ciphers)
☒ Custom SSL Cipher Selection

Show Selected Ciphers

Encryption Strength option
Normally, the allowed encryption strength is enforced after an SSL session is established, so that a user that connects using a disallowed encryption strength will receive a web page describing the problem. The option below will prevent a browser with a weak cipher from establishing a connection. Changing this option will cause the web service to restart.

☐ Do not allow connections from browsers that only accept weaker ciphers

Key Exchange Options
If the Allowed Encryption Strength includes any DH ciphers, the system uses 1024bit DHE key exchange by default. The option below will increase key exchange strength to 2048bit DHE.

☒ Use 2048bit Diffie-Hellman key exchange

SSL Legacy Renegotiation Support option
When this option is enabled, renegotiation with clients and servers, which don't support the new TLS Renegotiation Info extension (defined in RFC 5746), will be allowed. When disabled, renegotiation with such clients and servers will not be allowed. Changing this option will cause the web service to restart.

☐ Enable support for SSL legacy renegotiation

Common options

SSL Handshake Timeout option
By default, the SSL handshake has a timeout of 60 seconds. Use the text box below to set a different value.

Timeout: seconds 10-600 seconds

Note that changing any of the above settings might restart some services in the Ivanti Policy Secure.

[Save Changes](#)

Once you turn on FIPS level 1 support, the following changes are made:

- Under Allowed SSL and TLS Version, the **Accept only TLS** option is selected.
- Under Allowed Encryption Strength, **Maximize Compatibility (Medium Ciphers)** is set. Only FIPS approved ciphers are selected. See Supported Cipher Suites when FIPS Level 1 Support is Enabled and Disabled
- Under Encryption Strength, the **Do not allow connections from browsers that only accept weaker ciphers** option is selected.

3. Click **Save Changes**.

FIPS Level 1 support is now enabled on the device. If your browser does not support any of the listed ciphers, you will not be able to log in to the device.

When enabling FIPS mode on IPS, only the following protocols are FIPS compliant:

- EAP-TTLS
- EAP-PEAP
- EAP-TLS

A warning is displayed if non-FIPS protocols are configured on an IPS FIPS enabled device. However, these protocols are not disabled as they may be required for other use cases such as for the MAC authentication bridge.

Entries are made in the Events logs to show that FIPS level 1 support is enabled.

The screenshot displays the 'Log/Monitoring > Events > Logs' interface. It features a navigation bar with tabs for 'Events', 'User Access', 'Admin Access', 'Sensors', 'Client Logs', 'SNMP', 'Statistics', and 'Advanced Settings'. Below this is a sub-navigation bar with 'Log', 'Settings', and 'Filters'. The main area shows a 'View by filter' dropdown set to 'Standard:Standard (default)' and a 'Show 200 items' button. There is an 'Edit Query' input field and buttons for 'Update', 'Reset Query', and 'Save Query...'. Below these are buttons for 'Save Log As...', 'Clear Log', 'Save All Logs', and 'Clear All Logs'. A summary box shows 'Filter:Standard (default)', 'Date:Oldest to Newest', 'Query:', and 'Export Format:Standard'. The log entries are as follows:

Severity	Event ID	Timestamp	Source	Message
Info	SYS30966	2012-11-11 21:32:20	ive - [127.0.0.1] System()	FIPS Mode Set for web server
Minor	SYS10306	2012-11-11 21:32:19	ive - [127.0.0.1] System()	Starting services: web server
Info	ADM30965	2012-11-11 21:32:13	ive - [127.0.0.1] System()	FIPS Mode is now turned on. The web server will restart.

SSL FIPS Mode option

Enabling Inbound SSL Options

Only when FIPS mode is turned on, the FIPS compliant ciphers are available to be chosen from the Supported Ciphers panel. FIPS mode is editable only on the inbound option page.

To set the security options with Inbound SSL Options:

1. In the admin console, select **System > Configuration > Security > Inbound SSL Options**.
2. Under Allowed Encryption Strength choose Custom SSL Cipher Selection. See the following figure.

The following figure depicts the Setting Custom SSL Cipher Selections:

Allowed Encryption Strength

Strong ciphers (rated by the number of bits in the cipher) improve the security of SSL encryption, but some browsers may only support 40-bit ciphers. When there is more than one acceptable cipher, the Ivanti Policy Secure will give preference to the cipher with the fastest data transfer rate, regardless of its relative encryption strength. Changing the encryption strength will cause the web service to restart. Please see the Setting Security Options section in the Admin guide for more details.

- ☐ PFS - Perfect Forward Secrecy
- ☐ SuiteB - Accept only SuiteB ciphers (Requires an ECC certificate)
- ☐ CNSA1 - Accept only CNSA 1.0 ciphers
- ☐ Maximize Security (High Ciphers)
- ☐ Maximize Compatibility (Medium Ciphers)
- ☒ Custom SSL Cipher Selection

CNSA1.0 Requirements

For CNSA1.0 you need to consider following requirements and click **Change Allowed Encryption Strength**.

The ciphers selected for CNSA1.0 are relatively stronger than SuiteB due to restrictions on key sizes of ciphers/security algorithms.

- P-384 for Elliptic curves
- Minimum of 3072 bits for DHE and RSA algorithms.
- 256 bits for AES encryption
- 384 bits for SHA (hashing/compression)

CNSA1.0. complies the below ciphers.

- TLS_AES_256_GCM_SHA384 (TLSv1.3 only)
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_RSA_WITH_AES_256_GCM_SHA384
- TLS_DHE_RSA_WITH_AES_256_GCM_SHA384

For using EC algorithms, the device certificate has to be generated with P-384 key and signed with SHA-384 by the CA (Certifying Authority).

For using RSA certs, the device certificate has to be generated with a key size of 3072 bits or higher and signed with SHA-384 by the CA (Certifying Authority).

Usage of keys that are 3072 bits and higher is expected to increase the handshake duration. However, the elliptic curve algorithms are preferable due to the smaller key size of 384 bits.

1. The two panels of **Supported Ciphers** and **Selected Ciphers** are displayed. Supported ciphers has the entire list of ciphers supported for the selected SSL or TLS version. Selected ciphers list the currently selected ciphers list. The following figure shows the two panels (Supported Ciphers and Selected Ciphers). Note that the Selected Ciphers and Supported Ciphers List will also be displayed for all Preset like PFS or SuiteB or Medium or High.

The following figure depicts the Supported Ciphers and Selected Ciphers Panels:

Inbound SSL Options Outbound SSL Options Health Check Options Miscellaneous

SSL FIPS Mode option
 When this option is enabled, the web service will be placed in FIPS Mode, the cipher strength will be set to Medium, and all non-FIPS ciphers will be disabled. The current cipher customization might be lost. The web service will restart. FIPS mode is a prerequisite for NDcPP Mode.

☐ Turn on FIPS mode

Inbound Settings

Allowed SSL and TLS Version
 The older SSL V2 protocol has known security issues addressed by SSL V3 and TLS. It is no longer supported.

☒ Enable TLS 1.3
☒ Accept only TLS 1.3 (maximize security)
☐ Accept only TLS 1.2 and later
☐ Accept only TLS 1.1 and later
☐ Accept only TLS 1.0 and later
☐ Accept SSL V3 and TLS (maximize compatibility)

Allowed Encryption Strength
 Strong ciphers (rated by the number of bits in the cipher) improve the security of SSL encryption, but some browsers may only support 40-bit ciphers. When there is more than one acceptable cipher, the Ivanti Connect Secure will give preference to the cipher with the fastest data transfer rate, regardless of its relative encryption strength. Changing the encryption strength will cause the web service to restart. Please see the Setting Security Options section in the Admin guide for more details.

☐ PFS - Perfect Forward Secrecy
☐ SuiteB - Accept only SuiteB ciphers (Requires an ECC certificate)
☐ CNSA1 - Accept only CNSA 1.0 ciphers
☐ Maximize Security (High Ciphers)
☐ Maximize Compatibility (Medium Ciphers)
☒ Custom SSL Cipher Selection

Supported Ciphers

- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA

Selected Ciphers

- TLS_RSA_WITH_AES_256_GCM_SHA384
- TLS_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256

2. To add a cipher to be used in order to secure a connection, click on the cipher string on the left panel and then click on the Add> or double click on the cipher name in the left panel. See the following figure.

3. To remove the cipher, click on the cipher name on the right panel and then click on the <Remove button or double click on the cipher name on the right side. See the following figure.

4. The selected ciphers on the right are listed in order of their priority from top to bottom. To change the priority of the ciphers, click on the cipher name and then click on Move Up to increase priority or the Move Down button to decrease the priority. See the following figure.

The following figure depicts the Setting Custom SSL Cipher Selections:

► Show Selected Ciphers
Note: Custom cipher selection disables the Encryption Strength option.

Supported Ciphers	Selected Ciphers
TLS_RSA_WITH_AES_256_CBC_SHA256	TLS_RSA_WITH_AES_256_GCM_SHA384
TLS_RSA_WITH_AES_256_CBC_SHA	TLS_RSA_WITH_AES_128_GCM_SHA256
TLS_RSA_WITH_3DES_EDE_CBC_SHA	TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384
TLS_RSA_WITH_AES_128_CBC_SHA256	TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
TLS_RSA_WITH_AES_128_CBC_SHA	TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA	TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	TLS_DHE_RSA_WITH_AES_256_CBC_SHA
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	TLS_DHE_RSA_WITH_AES_128_CBC_SHA
	TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256

5. Select Key Exchange to increase the key exchange strength, default is 2048 bit key, you can increase the strength till 8192. The selected key size is the minimum key size supported in Ivanti Connect Secure. This works if following ciphers are selected:

- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- DHE-RSA-AES256-GCM-SHA384 (in openssl-3.0)

Key Exchange Options

If the Allowed Encryption Strength includes any DH ciphers, the system uses 2048bit DHE key exchange by default. The options below will increase key strength to 8192bit DHE. The selected key size will be the minimum key size supported in Ivanti Connect Secure.

- ☒ 2048
☐ 3072
☐ 4096
☐ 6144
☐ 8192

6. Select Enable port redirection for TLSv1.3 certificate authentication to allow client-certificate authentication over TLSv1.3 connections for browsers/clients that do not support Post Handshake Authentication (PHA). Changes to network configuration might be required so that the specified port is accessible to the client..

Client certificate authentication with redirection (TLSv1.3 only)

Certificate based authentication with TLSv1.3 protocol requires clients to support "PHA" (Post Handshake Authentication, RFC 8740). If client does not support PHA, this option can be enabled. When enabled, certificate authentication requests are momentarily redirected to an alternate port on ICS for completing authentication. Changing this option will cause the web service to restart.

☒ Enable port redirection for TLSv1.3 certificate authentication

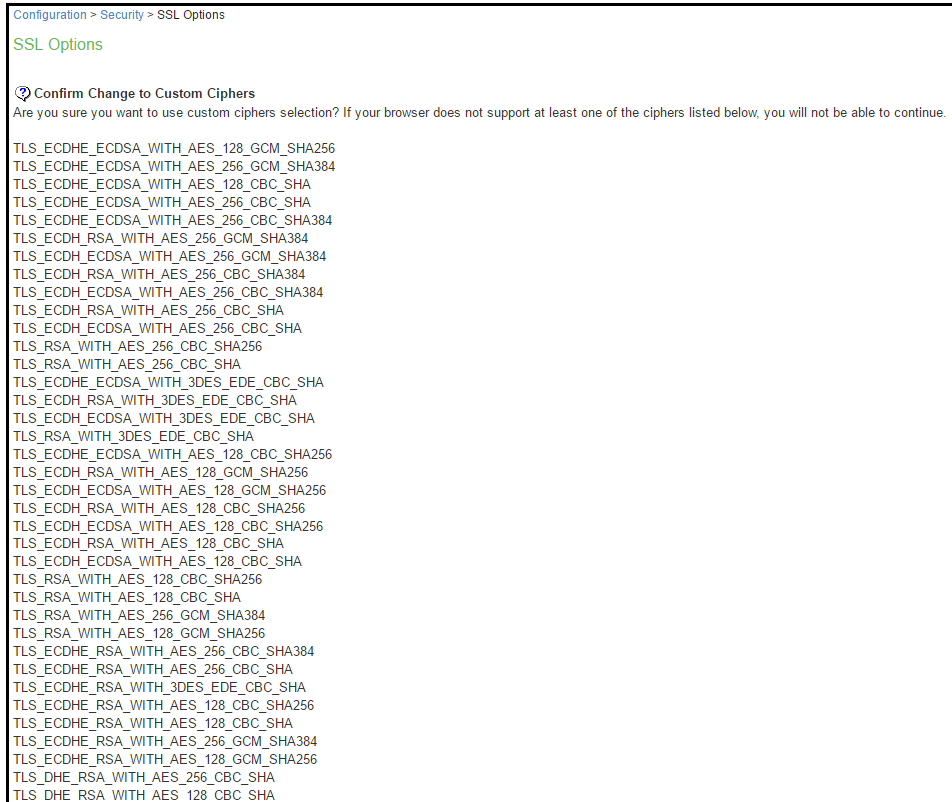

Port:

7. Select Allow legacy certificates for end to end communications to enable legacy certificates without certain attributes to be allowed with OpenSSL-3.

9. Click Save Changes.

A list of the custom ciphers to be used on the device's port is displayed in the order the web server will select them. Note that Suite B ciphers are listed on top. See the following table that depicts end users who now log in to external virtual port p_ecdsa256 must have at least one of the listed ciphers installed on their browser or else they cannot log in to the server.

The following figure depicts Confirming Custom Ciphers:

10. Click Change Allowed Encryption Strength.

When custom ciphers are selected, there is a possibility that some ciphers are not supported by the web browser. Also, if any of ECDH/ECDSA ciphers are selected, they require ECC certificate to be mapped to the internal/external interface. If ECC certificate is not installed, admin may not be able to log in to the box. The only way to recover from this situation is to connect to the system console and select option 8 to reset the SSL settings from the console menu. Option 8 resets the SSL settings to its default. So, the previously set SSL settings are lost. This is applicable only to Inbound SSL settings.

Ivanti Secure Access Client does not connect to the device if the ciphers selected in Inbound option are not supported by the mobile client.

Enabling Outbound SSL Options

Only for Outbound SSL Settings, we can configure Non FIPS Ciphers when FIPS is Enabled using Custom Cipher Selection Option. Now, there are options to change different SSL/TLS versions and different encryptions in the Outbound SSL Settings. The following figure shows the Outbound SSL Settings.

Outbound SSL Settings

The following table lists the SSL Options Configuration Guidelines:

Settings	Guidelines
SSL FIPS Mode option	Enable FIPS mode. See the Connect Secure FIPS Level 1 Feature Guide
Allowed SSL and TLS Version	Specify encryption requirements for clients. By default, the system requires SSL version 3 and TLS. The system honors this setting for all Web server traffic and all types of clients. You can require users who have older browsers that use SSL version 2 to update their browsers, or you can change this setting to allow SSL version 2, SSL version 3, and TLS.
Allowed Encryption Strength	Accept only 128-bit and greater-The default. The system gives preference to RC4 ciphers. You can require users to have this level of encryption strength or change this default to an option compatible with the user base. Accept only 168-bit and greater-The system gives preference to 256-bit AES over 3DES. Accept 40-bit and greater-The system gives preference to RC4 ciphers. Older browsers that predate the change in the U.S. export law in year 2000 that required 40-bit cipher encryption for international export, can still use 40-bit encryption. Custom SSL Cipher Selection-Specify a combination of cipher suites for the incoming connection from the user's browser. If you select the AES/3DES option, the system gives preference to 256-bit AES over 3DES. When using 168-bit encryption, some Web browsers may still show 128-bit encryption (the gold lock on the browser status bar) even though the connection is 168-bit. This is typically a limitation of the browser's capability. If you are using the IC6500 FIPS version, you can choose High, Medium, or Low security cipher suites. AES/3DES High and AES Medium are recommended for FIPS deployment.
Encryption Strength option	Normally, the allowed encryption strength is enforced after an SSL session is established, so that a user connecting with a disallowed encryption strength

	receives a Web page describing the problem. Enable this option to prevent a browser with a weak cipher from establishing a connection.
SSL Handshake Timeout option	Determines how many seconds elapse before the SSL handshake times out. The default is 60 seconds.
SSL Legacy Renegotiation Support option	SSL and Transport Layer Security (TLS) renegotiations can be subjected to man-in-the-middle (MITM) attacks that can lead to abuse. A new TLS extension (defined in RFC 5746) ties renegotiations to the TLS connections they are being performed over to prevent these kinds of attacks. The SSL Legacy Renegotiation Support option is enabled by default and allows renegotiation between clients and servers even if they do not support the new TLS extension. Disable this option to not allow renegotiations between clients and servers that do not support the new TLS extension. A web server restart is required when you change the value of this option.
ActiveSync Client Certificate Configuration	Use these controls to enforce client certificate requirement for activesync access on the selected ports, including virtual ports. When enabled, all ActiveSync clients must present a client authentication certificate to the system to be able to connect using ActiveSync. Non-ActiveSync access (like web browser-based access to the host, NC, JSAM, PSAM, Ivanti, WTS, IKEv2 and so forth) on the port/interface on which the ActiveSync client certificate is required might not work properly. We recommend you use a separate port or interface exclusively for ActiveSync access and then enable client certificate requirement for the port intended for ActiveSync access.

SSL NDcPP Mode Option

NDcPP mode can be enabled in the Inbound tab with a check box. This status is also applied over to the Outbound tab. Turning on NDcPP automatically turns on FIPS mode and disables SSL/TLS Version TLS1.0 and below. Also, NDcPP Mode allows to choose only 16 Ciphers under Custom Encryption Strength. Turning on the NDcPP check box selects all the NDcPP ciphers by default on both, the Inbound and Outbound sides.

When the NDcPP Mode is enabled, backend server like Windows 2008 R2 which supports the SSL/TLS Version only till TLS1.0 cannot be connected via Rewriter.

syslog-ng server

- Connection to syslog-ng server does NOT get established, since syslog-ng does not support TLSv1.1 and TLSv1.2.

rsyslog

- Supports only till TLSv1.1. So, connection would not get established, if Outbound SSL Options is set to use TLSv1.2.

To be NDcPP compliant, NTP Update Interval needs to be limited to 60 minutes. This is to avoid the potential drift becoming too excessive.

For incoming client certificate during client certificate authentication and for incoming server certificate during backend syslog server connection 1024-bit Key Length is not allowed in both NDcPP and FIPS Mode where as SHA1 Signature Algorithm is not allowed only in FIPS Mode and is allowed in NDcPP Mode. This restriction is not applicable for Outgoing Certificates from during SSL Negotiation.

The following figure depicts the SSL NDcPP Mode Option:

SSL Options

Configuration

Security

Licensing **Security** Certificates DMI Agent NCP Client Types Virtual Desktops User Record Synchronization IKEV2 SAML Mobile VPN Tunneling PSAM Telemetry

Advanced Client Configuration Advanced Networking

Inbound SSL Options Outbound SSL Options Health Check Options Miscellaneous Advanced

DoD Certification option

When this option is enabled, the web service will be placed in JITC Mode. NDcPP and FIPS Modes will also be turned on and all non-FIPS ciphers will be disabled. The web service will restart.

☐ Turn on JITC mode

SSL NDcPP Mode option

When this option is enabled, the web service will be placed in NDcPP Mode. FIPS Mode will also be turned on and all non-FIPS ciphers will be disabled. The web service will restart. NDcPP Mode is a prerequisite for JITC Mode.

☐ Turn on NDcPP mode

SSL FIPS Mode option

When this option is enabled, the web service will be placed in FIPS Mode, the cipher strength will be set to Medium, and all non-FIPS ciphers will be disabled. The current cipher customization might be lost. The web service will restart. FIPS mode is a prerequisite for NDcPP Mode.

☒ Turn on FIPS mode

Admin Password Storage

NDcPP mandates that admin passwords needs to be scrambled with SHA2 algorithm. So, current SHA1 password scrambling is no longer supported. Password migration is done through double hashing. Existing scrambled passwords stored in the cache are scrambled again with SHA 512.

New passwords will be hashed twice: first with SHA1 and then with SHA512 and then, stored in the cache.

Inbound Settings

When the NDcPP mode is enabled, the following settings appear by default in the Inbound SSL Options page:

- The Accept only TLS 1.1 and later is enabled by default in the Allowed SSL and TLS Version settings. Only the Accept only TLS 1.1 and Accept only TLS 1.2 options can be chosen. The Accept only TLS 1.0 and later and the Accept SSL V3 and TLS (maximize compatibility) are disabled. See the following figure.
- With regards to the Allowed Encryption Strength settings the Custom SSL Cipher Selection is enabled by default with NDcPP Ciphers. All other options are disabled.

The following figure depicts the NDcPP Inbound Settings Page:

SSL NDcPP Mode option

When this option is enabled, the web service will be placed in NDcPP Mode. FIPS Mode will also be turned on and all non-FIPS ciphers will be disabled. The web service will restart. NDcPP Mode is a prerequisite for JITC Mode.

☒ Turn on NDcPP mode

SSL FIPS Mode option

When this option is enabled, the web service will be placed in FIPS Mode, the cipher strength will be set to Medium, and all non-FIPS ciphers will be disabled. The current cipher customization might be lost. The web service will restart. FIPS mode is a prerequisite for NDcPP Mode.

☒ Turn on FIPS mode

Inbound Settings

Allowed SSL and TLS Version

The older SSL V2 protocol has known security issues addressed by SSL V3 and TLS. It is no longer supported.

- ☐ Enable TLS 1.3
- ☐ Accept only TLS 1.2
- ☒ Accept only TLS 1.1 and later
- ☐ Accept only TLS 1.0 and later
- ☐ Accept SSL V3 and TLS (maximize compatibility)

Allowed Encryption Strength

Strong ciphers (rated by the number of bits in the cipher) improve the security of SSL encryption, but some browsers may only support 40-bit ciphers. When there is more than one acceptable cipher, the Ivanti Connect Secure will give preference to the cipher with the fastest data transfer rate, regardless of its relative encryption strength. Changing the encryption strength will cause the web service to restart. Please see the Setting Security Options section in the Admin guide for more details.

- ☐ PFS - Perfect Forward Secrecy
- ☐ SuiteB - Accept only SuiteB ciphers (Requires an ECC certificate)
- ☐ CNSA1 - Accept only CNSA 1.0 ciphers
- ☐ Maximize Security (High Ciphers)
- ☐ Maximize Compatibility (Medium Ciphers)
- ☒ Custom SSL Cipher Selection

The following is a list of Selected Ciphers in the Inbound Settings with the NDcPP mode enabled:

- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA

- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384

The following figure depicts the Selected Ciphers in the Inbound Settings with the NDcPP Mode:

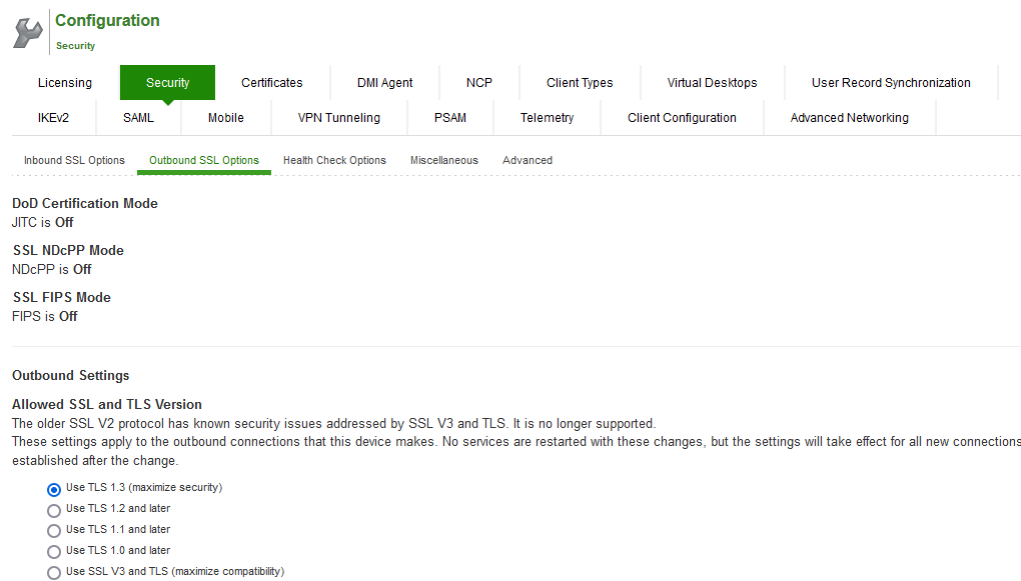

Outbound Settings

When the NDcPP mode is enabled, the following settings appear by default in the Outbound SSL Options page:

- The Accept only TLS 1.1 and later is enabled by default in the Allowed SSL and TLS Version settings. Only the Accept only TLS 1.1 and Accept only TLS 1.2 are editable. The Accept only TLS 1.0 and later and the Accept SSL V3 and TLS (maximize compatibility) are disabled.
- With regards to the Allowed Encryption Strength settings the Custom SSL Cipher Selection is enabled by default. All other options are disabled.
- Only the NDcPP ciphers configured in the Outbound SSL options settings are sent in the Outbound connections (PCS -> backend SSL).

The following figure depicts the NDcPP Outbound Settings Page:

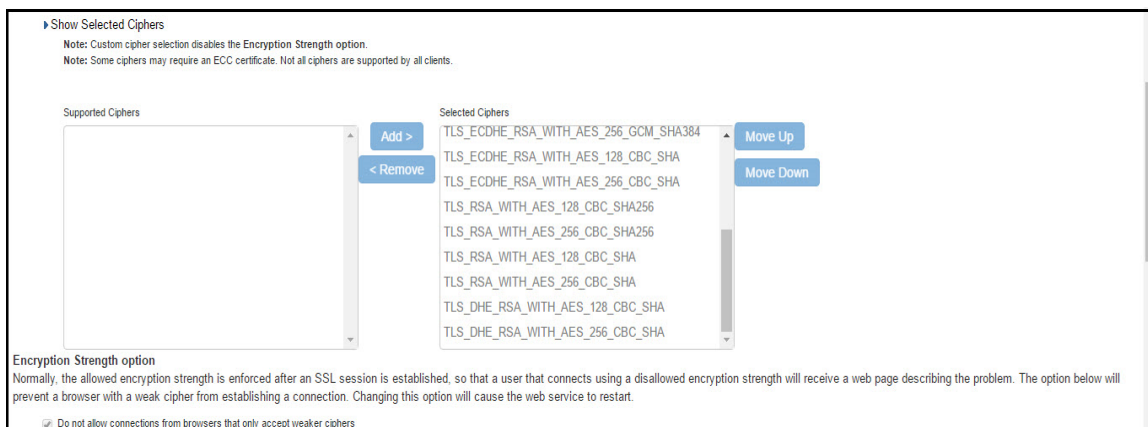

The following is a list of Selected Ciphers in the Outbound Settings with the NDcPP mode enabled:

- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA

- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384

The following figure depicts the Selected Ciphers in the Outbound Settings with the NDcPP Mode:

Security Hardening

Security Enhanced (SELinux) Support

This feature constraints access to the IPS Linux system (IPS Linux applications) with the minimal set of resources they need.

1. In the serial console, enter 13 to select Security Operations(SELinux).

```
Welcome to the Ivanti Policy Secure Serial Console!
```

```
Current version: 22.7R1 (build 1067)
```

```
Rollback version: 22.5R1 FIPS (build 553)
```

```
Reset version: 22.4R1 FIPS (build 373)
```

```
Licensing Hardware ID: VASPHX1WH05YS0KAE
```

```
Please choose from among the following options:
```

1. Network Settings and Tools
2. Create admin username and password
3. Display log/status
4. System Operations
5. Toggle password protection for the console (Off)
6. Create a Super Admin session
7. System Maintenance
8. Reset allowed encryption strength for SSL
99. Enable/Disable Kernel Logging
13. Security Operations

```
Choice: 13
```

2. Choose the SELinux mode: This feature is enabled by default with system running in enforcing mode. To change the mode enter 1 and choose the following options:

- Permissive: SELinux logs each system call, but does not filter access requests.
- Enforcing: As each system call is received, SELinux logs it and filters it according to the security policies configured. Security policies determine whether access is allowed or denied by SELinux.

SE Linux cannot be disabled.

```
13. Security Operations
Choice: 13

Please choose from among the following options:
  1. Change SELinux mode
  <return to go back to main menu>
Choice: 1
Current SELinux mode: Enabled (Enforcing)

Please choose from among the following options:
  1. Permissive
  2. Enforcing
  <return to go back to main menu>
Choice:
```

Audit Logs

A snapshot of the system state captures details that can help Support Center diagnose system performance problems. The system stores up to ten snapshots, which are packaged into an encrypted "dump" file that you can download and then e-mail to Global Support Center.

To enable Audit Logs:

1. Select Maintenance > Troubleshooting > System Snapshot to display the configuration page.
2. Click the checkbox Include Audit Log under System snapshot options.

▼ System snapshot options

☒ Include Audit Log

☒ Include system config

☒ Include debug log

☐ Include File Integrity data This option is non-persistent. This option should be enabled only in off-hours to reduce production impact

☐ Schedule automatic snapshots

[Save Changes](#)

Enable SELinux Audit Logs

SELinux audit logs can be very useful for finding out security attacks via SELinux denials and also for debugging purpose.

Sample SELinux denial message

```
type=AVC msg=audit(1223024155.684:49): avc: denied { getattr } for pid=2000 comm="httpd"
path="/var/www/html/file1" dev=dm-0 ino=399185 scontext=unconfined_u:system_r:httpd_t:s0
tcontext=system_u:object_r:samba_share_t:s0 tclass=file
```

TLS 1.3 Support

To enable TLS 1.3:

1. Select the checkbox Enable TLS 1.3, under Inbound Settings Allowed SSL and TLS Version

TLS for certAuth would be TLS 1.2 even if TLS 1.3 is selected by admin. Note that connection between server and client still would be TLS 1.3. TLS 1.2 is only used for inner TLS (To send as payload in TLS 1.3 packets).

Inbound Settings

Allowed SSL and TLS Version

The older SSL V2 protocol has known security issues addressed by SSL V3 and TLS. It is no longer supported.

- ☒ Enable TLS 1.3
- ☐ Accept only TLS 1.3 (maximize security)
- ☒ Accept only TLS 1.2 and later
- ☐ Accept only TLS 1.1 and later
- ☐ Accept only TLS 1.0 and later
- ☐ Accept SSL V3 and TLS (maximize compatibility)

2. While enforcing TLS 1.3 the following Confirm Cipher Change message is displayed.

Confirm Cipher Change

Note that changing any of these settings might restart some services. Do you want to proceed?

Older clients will fail to establish the session when TLS1.3 is enabled for Inbound SSL options. For more details, refer to [Impact on Client Launches](#).

Browser based Client certificate authentication may not work with all browsers with TLS 1.3 enabled. For more details, refer to [Impact on Browser based Cert Auth](#).

Proceed

Cancel

Older clients will fail to establish the session when TLS1.3 is enabled for Inbound SSL options. For more details, refer to [Impact on Client Launches](#).

Browser based Client certificate authentication may not work with all browsers with TLS 1.3 enabled. For more details, refer to [Impact on Browser based Cert Auth](#).

- On selecting Accept only TLS 1.3 option, only TLS1.3 version and its related ciphers are enabled while other versions and their related cipher suites are rejected.

Inbound Settings

Allowed SSL and TLS Version

The older SSL V2 protocol has known security issues addressed by SSL V3 and TLS. It is no longer supported.

- ☐ Enable TLS 1.3
- ☒ Accept only TLS 1.3 (maximize security)
- ☐ Accept only TLS 1.2 and later
- ☐ Accept only TLS 1.1 and later
- ☐ Accept only TLS 1.0 and later
- ☐ Accept SSL V3 and TLS (maximize compatibility)

Release 22.7R1 and later does not support weak ciphers and the following list of ciphers are removed:

- TLS_ECDH_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDH_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDH_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDH_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDH_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDH_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDH_RSA_WITH_AES_256_CBC_SHA384
- TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA384
- TLS_ECDH_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDH_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDH_ECDSA_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_WITH_RC4_128_MD5

- SSL_RSA_WITH_RC4_128_SHA
- TLS_ECDH_ECDSA_WITH_RC4_128_SHA
- TLS_ECDHE_ECDSA_WITH_RC4_128_SHA
- TLS_ECDH_RSA_WITH_RC4_128_SHA
- TLS_ECDHE_RSA_WITH_RC4_128_SHA

Enabling Granular Cipher Selection for Setting the Security Options

Granular cipher selection provides an administrator the ability to select specific ciphers and the preferred ordering of the selected ciphers. This feature also provides presets like Suite-B and PFS. There are two tabs, Inbound OpenSSL options and Outbound OpenSSL options. With this feature the administrator can select the ciphers that TLS/SSL connections will use. The Inbound OpenSSL options apply to all incoming connections. Outbound OpenSSL options apply to the following services:

- SCEP
- Syslog
- LDAPS
- Start TLS

FIPS Mode Settings is common for both Inbound and Outbound SSL Options.

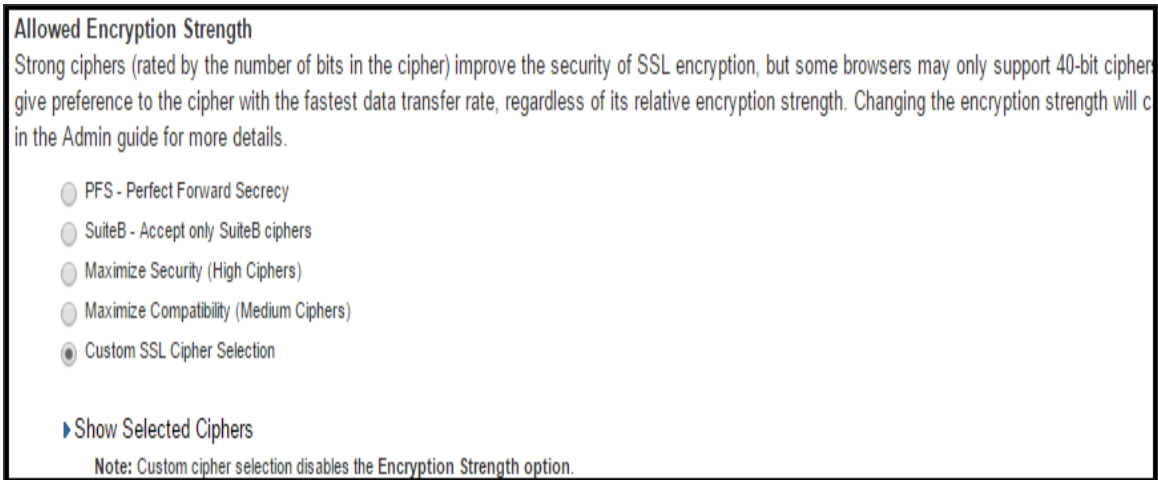

A common cipher library has been added which can be used by both, the inbound and outbound connections. The outbound options are listed in a separate tab next to the inbound settings. The outbound settings have presets for High and Medium ciphers along with custom options. There is no PFS or SuiteB presets on the outbound side. From 5.3R3 release onwards, support for preset Low has been removed and the same can be configured using Custom SSL Cipher Selection option. For the SuiteB preset to work, IPS should have ECC Device Certificate mapped to Internal or External Port. SuiteB preset does not work if the ECC Device Certificate is mapped only to virtual port.

Enabling Inbound SSL Options

Only when FIPS mode is turned on, the FIPS compliant ciphers are available to be chosen from the Supported Ciphers panel. FIPS mode is editable only on the inbound option page.

To set the security options with Inbound SSL options:

1. In the admin console, select **System > Configuration > Security > Inbound SSL Options**.
2. Under **Allowed Encryption Strength** choose **Custom SSL Cipher Selection**.

The two panels of Supported Ciphers and Selected Ciphers are displayed. Supported ciphers has the entire list of ciphers supported for the selected SSL or TLS version. Selected ciphers list the currently selected ciphers list. The below figure shows the two panels (Supported Ciphers and Selected Ciphers). Note that the Selected Ciphers and Supported Ciphers List will also be displayed for all Preset like PFS or SuiteB or Medium or High.

Inbound SSL Options
Outbound SSL Options
Health Check Options
Miscellaneous

SSL FIPS Mode option

When this option is enabled, the web service will be placed in FIPS Mode, the cipher strength will be set to Medium, and all non-FIPS ciphers will be disabled. The current cipher customization might be lost. The web service will restart. FIPS mode is a prerequisite for NDCPP Mode.

☐ Turn on FIPS mode

Inbound Settings

Allowed SSL and TLS Version

The older SSL V2 protocol has known security issues addressed by SSL V3 and TLS. It is no longer supported.

☒ Enable TLS 1.3

☒ Accept only TLS 1.3 (maximize security)

☐ Accept only TLS 1.2 and later

☐ Accept only TLS 1.1 and later

☐ Accept only TLS 1.0 and later

☐ Accept SSL V3 and TLS (maximize compatibility)

Allowed Encryption Strength

Strong ciphers (rated by the number of bits in the cipher) improve the security of SSL encryption, but some browsers may only support 40-bit ciphers. When there is more than one acceptable cipher, the Ivanti Connect Secure will give preference to the cipher with the fastest data transfer rate, regardless of its relative encryption strength. Changing the encryption strength will cause the web service to restart. Please see the Setting Security Options section in the Admin guide for more details.

☐ PFS - Perfect Forward Secrecy

☐ SuiteB - Accept only SuiteB ciphers (Requires an ECC certificate)

☐ CNSA1 - Accept only CNSA 1.0 ciphers

☐ Maximize Security (High Ciphers)

☐ Maximize Compatibility (Medium Ciphers)

Encryption Strength option

Normally, the allowed encryption strength is enforced after an SSL session is established, so that a user that connects using a disallowed encryption strength will receive a web page describing the problem. The option below will prevent a browser with a weak cipher from establishing a connection. Changing this option will cause the web service to restart.

☒ Do not allow connections from browsers that only accept weaker ciphers

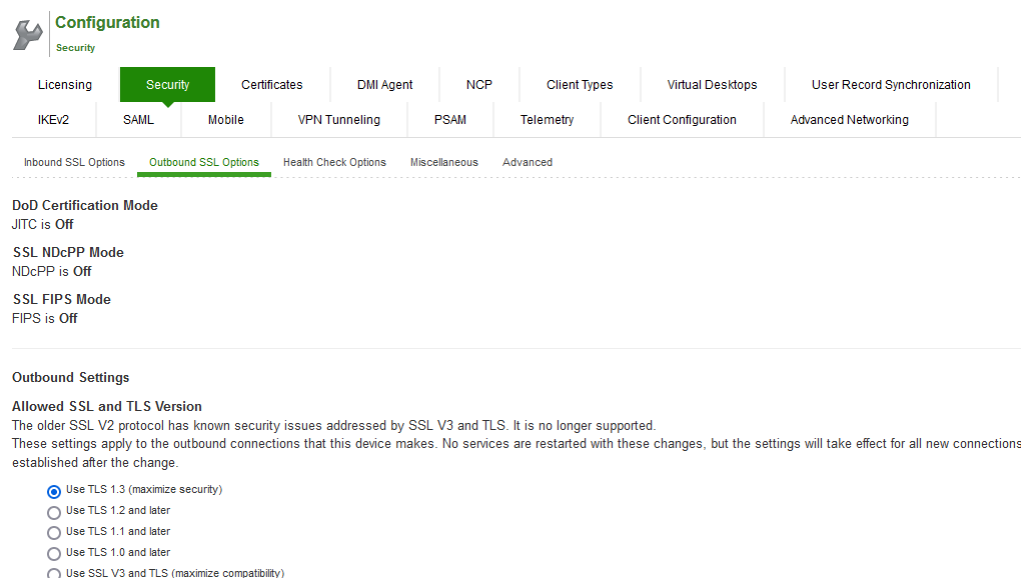

Click **Change Allowed Encryption Strength**.

When custom ciphers are selected, there is a possibility that some ciphers are not supported by the web browser. Also, if any of ECDH/ECDSA ciphers are selected, they require ECC certificate to be mapped to the internal/external interface. If ECC certificate is not installed, administrator may not be able to log in to the box. The only way to recover from this situation is to connect to the system console and select option 8 to reset the SSL settings from the console menu. Option 8 resets the SSL settings to its default. So, the previously set SSL settings are lost. This is applicable only to Inbound SSL settings.

Enabling Outbound SSL Options

We can configure non FIPS ciphers only for Outbound SSL Settings using Custom Cipher Selection option. There are options to change different SSL/TLS versions and different encryptions in the Outbound SSL Settings. The below figure shows the Outbound SSL Settings

Settings	Guidelines
SSL FIPS Mode option	Turn on FIPS mode— Select this option to enable FIPS mode.

Settings	Guidelines
Allowed SSL and TLS Version	Specify encryption requirements for clients. By default, the system requires SSL version 3 and TLS. The system honors this setting for all Web server traffic and all types of clients. You can require users who have older browsers that use SSL version 2 to update their browsers, or you can change this setting to allow SSL version 3, and TLS.
Allowed Encryption Strength	<ul style="list-style-type: none"> Accept only 168-bit and greater — If you select this option the system gives preference to 256-bit AES over 3DES. Accept only 128-bit and greater — (Default) If you select this option the system gives preference to RC4 ciphers. You can require users to have this level of encryption strength or change this default to an option compatible with the user base. Accept 40-bit and greater — If you select this option the system gives preference to RC4 ciphers. Older browsers that predate the change in the U.S. export law in year 2000 that required 40-bit cipher encryption for international export, can still use 40-bit encryption. Custom SSL Cipher Selection — Specify a combination of cipher suites for the incoming connection from the user's browser. If you select the AES/3DES option, the system gives preference to 256-bit AES over 3DES. <hr/> <div>  <p>When using 168-bit encryption, some Web browsers may still show 128-bit encryption (the gold lock on the browser status bar) even though the connection is 168-bit. This is typically a limitation of the browser's capability.</p> </div> <hr/>
Encryption Strength option	The allowed encryption strength is enforced after an SSL session is established, so that a user connecting with a disallowed encryption strength receives a Web page describing the problem. Enable this option to prevent a browser with a weak cipher from establishing a connection.
SSL Handshake Timeout option	Determines the time elapse before the SSL handshake timeout. The default is 60 seconds.

Settings	Guidelines
SSL Legacy Renegotiation Support option	SSL and Transport Layer Security (TLS) renegotiations can be subjected to man-in-the-middle (MITM) attacks that can lead to abuse. A new TLS extension (defined in RFC 5746) ties renegotiations to the TLS connections they are being performed over to prevent these kinds of attacks. The SSL Legacy Renegotiation Support option is enabled by default and allows renegotiation between clients and servers even if they do not support the new TLS extension. Disable this option to not allow renegotiations between clients and servers that do not support the new TLS extension. A web server restart is required when you change the value of this option.

Configuring Health Check Options

You can use the **System > Configuration > Security > Health Check Options** page to configure the following security options:

- **Enable additional information via healthcheck.cgi**—This option is used by entities like load balancers to monitor the health status of the node.

To configure health check options:

1. Select **System > Configuration > Security > Health Check Options** to display the configuration page.

Network > Internal > Internal Port - ARP Cache

Internal Port - ARP Cache

Network Settings
Internal Port - ARP Cache

Overview Internal Port External Port Management Port VLANs Routes Hosts Load Balancer

Settings Virtual Ports ARP Cache ND Cache

This shows the current ARP table for this port. These mappings are automatically created, but if necessary, you can add or remove entries.

Delete... Delete Dynamic Entries

	IP Address	Physical Address	Type	
	<input type="text"/>	<input type="text"/>		<input type="button" value="Add"/>
<input type="checkbox"/>	10.204.88.1	00:1F:12:35:64:40	Dynamic	
<input type="checkbox"/>	10.204.89.92	00:10:DB:FF:10:07	Dynamic	
<input type="checkbox"/>	10.204.91.254	00:26:88:6E:CE:01	Dynamic	

2. Select the Enable additional information via healthcheck.cgi checkbox and **Save Changes**. A URL parameter 'status' needs to be passed to get additional information to the health check URL. For more information about parameters such as CPU usage and number of active sessions use <https://<Ivanti Policy Secure>/dana-na/healthcheck/healthcheck.cgi?status=all>. For more information about SBR statistics use <https://<Ivanti Policy Secure>/dana-na/healthcheck/healthcheck.cgi?status=sbr>
3. Enter the IPv4/v6 address of the load balancer and click **Add**.
4. Click **Save Changes**.

Configuring Miscellaneous Security Options

You can use the **System > Configuration > Security > Miscellaneous** page to configure the following security options:

- **Persistent cookie options**—Choose whether to preserve or delete persistent cookies when a session is terminated.
- **Lockout options**—You can configure lockout options to protect the system from denial of service (DoS), distributed denial of service (DDoS), and password-guessing attacks.
- **Slow Post Attack Defense** - You can configure to protect against slow-post DOS attacks from non-authenticated users.

- **Integrity checking options** - You can configure scan the system to periodically check for any integrity anomalies. If any anomaly found, information is displayed in the dashboard.

On low-end machines, a reduction in through-put may be seen. To overcome such issues, opt for scheduled scan option in off-peak hours.

To configure cookie and lockout options:

1. Select System > Configuration > Security > Miscellaneous to display the configuration page.

The following figure shows the configuration page.

2. Complete the configuration as described in the following table.

3. Save the configuration.

The following figure depicts the Miscellaneous Security Options Configuration Page:

Configuration > Security > Miscellaneous

Delete all cookies at session termination

For convenience, some persistent cookies (the last realm cookie and the last sign-in URL cookie) are set on the user's machine. If you desire additional security or privacy, you may choose to not set them.

☐ Delete all cookies at session termination (maximize security)
 ☒ Preserve cookies at session termination (maximize usability)

Lockout options

The following settings determine how failed sign-in attempts are handled. When the number of allowed attempts is exceeded, the IP or MAC address that is used for signing-in will be temporarily locked to prevent automated sign-in attempts.

Rate

3

per minute

1/2147483647 Rate of failed attempts

Attempts

100

2/2147483647 Initial trigger of failed attempts

Lockout period

2

minutes

1/10000 minutes

Slow post attack defence

The Slow Post Attack is a slow post HTTP attack, which is a kind of Denial-of-Service (DOS) attack in which the attacker slowly sends HTTP requests in small pieces, keeping server resources busy and making out concurrent connection pools. The following countermeasures are supported:

- Set a smaller maximum wait time (Timeout) for a unauthenticated post connection to complete.
- Set a smaller maximum request size. Unauthenticated requests exceeding set values will be dropped.

NOTE: Very small values for either parameter may result in legitimate requests being dropped. The settings should minimally be slightly higher than the default statistical means.

Timeout

10

Seconds

1 - 100 Seconds

Maximum request size

32768

Bytes

256 - 1048576 Bytes

HSTS

HTTP Strict Transport Security (HSTS) is a HTTP response header which will prevent any communications over HTTP and also prevents HTTPS click through prompts on browsers.

Max Age

365

Days

1 - 365 days

☐ Enable IncludeSubDomain directive
 ☐ Enable preload directive

Bootstrapping Options on Integrity Check Failure

According to OTC Configuration, the product should not start up if the SHA-256 verification of the manifest file or the SHA-256 verification of the executable file fails, this option is added to ensure this requirement is met. If this option is enabled, the system will continue to boot normally when the integrity check fails.

☐ Enabled this checkbox to provide options to Rollback, Rollback, or Continue Booting if integrity check fails for executable or manifest file during system boot-up.

Host Header Validation

☐ Enable Host header validation to block open redirect attacks (please check KB46466 before enabling this feature.)

Username Validation

☒ Enable Username validation to block unauthenticated access

Runtime Integrity Scanner Interval

☒ Periodic Scan
 ☐ Scheduled Scan

☐ Every 1 Hour
 ☒ Every 2 Hours
 ☐ Every 4 Hours
 ☐ Every 12 Hours
 ☐ Every 24 Hours

Referer Header Validation

☐ Enable Referer Header validation to block CSRF attacks

Active Directory Encryption type

☐ Enable AES 256 type encryption for Active Directory Authentication Server

NOTE: Choosing AES 256 type encryption might impact performance

Relay State Validation

☒ Enable RelayState Validation for SAML Authentication Server

Save Changes

To configure cookie and lockout options:

1. Select **System > Configuration > Security > Miscellaneous** to display the configuration page.
2. Complete the configuration as described in table.
3. Save the configuration.

Settings	Guidelines
Attempts	Specify the maximum number of failed sign-in attempts to allow before triggering the initial lockout. The system determines the maximum initial time (in minutes) to allow the failed sign-in attempts to occur by dividing the specified number of attempts by the rate. For example, 180 attempts divided by a rate of 3 results in an initial period of 60 minutes. If 180 or more failed sign-in attempts occur within 60 minutes or less, the system locks out the IP address being used for the failed sign-in attempt.
Lockout period	Specify the length of time (in minutes) the system must lock out the IP address.
Slow Post Attack Defence	
Timeout	By default, the POST body is received within 10 seconds. If the browser is unable to send the POST body within 10 seconds the connection is eventually dropped. (Configurable from 3 - 60Sec)
Maximum Request Size	By default, now a connection is directly rejected if it tries to POST more than 4KB in POST body (Configurable from 256 Bytes to 24 KB)
HSTS	
Max Age	Specify the maximum age for HSTS. It can be disabled by configuring max age as 0.
Enable include Subdomain directive	Select the check box to enable/disable the include Subdomain directive. By default, it is turned off.
Enable preload directive	Select the check box to enable/disable the preload directive. By default, it is turned off.
Bootimg Options on Integrity Check Failure	

Settings	Guidelines
Booting Options on Integrity Check Failure to stop booting if integrity validation fails for manifest file or any executable.	Select the check box to enforce booting options on integrity validation. By default, it is turned off. The following integrity checks are performed: <ul style="list-style-type: none"> • Checks the SHA512 digital signature of the manifest file. • Checks the SHA256 digest of each individual file entries in the manifest. If enabled and integrity check fails, admin gets an option to roll back to previous working package or perform factory reset or continue to boot
Host Header Validation	
Enable Host Header Validation to block open redirect attacks	Select the check box to enforce Host Header validation. By default, it is turned off. When Host header validation is enabled, every http request will be validated against hostnames and IP v4/v6 addresses known to the IPS server. If match is not found, the request will be dropped.
Active Directory Encryption type	
Enable AES 256 type encryption for Active Directory Authentication Server	Select the check box to enable AES256 encryption type. If enabled, this option changes the encryption type to AES256 for all Active Directory Authentication Server using Kerberos Authentication Protocol. This Feature is applicable only for Active Directory Authentication Server using Kerberos Authentication protocol.

Scenario Illustrating Lockout Settings Workflow

The following scenario illustrates how lockout settings work. For example, assume the following settings:

- **Rate** = 3 failed sign-in attempts per minute
- **Attempts** = 180 maximum allowed in initial period of 60 minutes (180/3)
- **Lockout period** = 2 minutes

The following sequence illustrates the effect of these settings:

- During a period of 3 minutes, 180 failed sign-in attempts occur from the same IP address. Because the specified value for Attempts occurs in less than the allowed initial period of 60 minutes ($180/3$), the system locks out the IP address for 2 minutes (fourth and fifth minutes).
- In the sixth minute, the system removes the lock on the IP address and begins maintaining the rate of 3 failed sign-in attempts/minute. In the sixth and seventh minutes, the number of failed sign-in attempts is 2 per minute, so the system does not lock the IP address. However, when the number of failed sign-in attempts increases to 5 in the eighth minute, which is a total of 9 failed sign-in attempts within 3 minutes, the system locks out the IP address for 2 minutes again (ninth and tenth minutes).
- In the eleventh minute, the system removes the lock on the IP address and begins maintaining the rate of 3 failed sign-in attempts per minute again. When the rate remains below an average of 3 per minute for 60 minutes, the system returns to its initial monitoring state.

Configuring Custom HTTP Headers

Ivanti Policy Secure (IPS) supports several HTTP headers, which are sent in response to the client request. There are several more headers built to improve security and prevent attacks like XSS. The Custom HTTP Headers configuration enables the administrator to add new headers that they want to enforce.

To configure custom HTTP header:

1. Select **System > Configuration > Security > Advanced**.
2. In the Custom HTTP Headers section, enter the HTTP header name and the directives along with the values.
3. Click **Add**.

- Multiple headers can be added or removed. After adding the headers, click **Save Changes**.

- Administrator should ensure the correctness of the values that they enter, as the system validation on the input values is limited
- If the administrator configured HTTP header seems to affect the way the page is rendered or is locked out, use the console option to reset the custom HTTP header values.

Using the Serial Port

This topic describes use of the serial port and serial port console. It includes the following information:

Connecting to the Serial Port Console

In cases where the admin console is unavailable, you can perform network and host configuration tasks and troubleshooting using the serial port console.

To connect to the serial console:

1. Plug a null modem crossover cable from a console terminal or laptop into the device serial port. This cable is provided in the product box. Do not use a straight serial cable.
2. Configure a terminal emulation utility, such as HyperTerminal, with the following serial connection parameters:
 - 9600 bits per second
 - 8-bit No Parity (8N1)
 - 1 Stop Bit
 - No flow control

Options	Description
1. Network Settings and Tools	Enables you to change standard network settings; print a routing table; print or clear an ARP cache; run the ping and traceroute commands, remove static routes, and add an ARP entry.
2. Create admin username and password	Enables you to create a new super administrator account.
3. Display log	Enables you to display system configuration, user access logs, or administrator access logs through the serial console. Note that must enter q to return to serial console options after viewing the logs.
4. System Operations	Enables you to reboot, shut down, restart, roll back, or factory reset the system without using the admin console.
5. Toggle password protection for the console	Enables you to password protect the serial console. When you toggle this option to "on," only super administrators are allowed access.
6. Create a Super Admin session	Enables you to create a recovery session to the admin console, even if you have configured the system to block access to all administrators. When you select this option, the system generates a temporary token that is valid for 3 minutes. Enter the following URL into a browser window:

Options	Description
	<p><code>https://<fully-qualified-domain-name>/dana-na/auth/recover.cgi</code></p> <p>Then, enter the temporary token when prompted to sign in to the admin console.</p> <p>When you select this option, the system blocks any additional administrators from signing in to the admin console until you sign in to the specified URL and initiate a session using your token. The appliance blocks additional sign-in attempts so that you can fix any configuration problems that the system may have encountered without conflicting with another session.</p>
7. System Snapshot	<p>Enables you to take a system snapshot without using the admin console. When you select this option, the system takes the snapshot immediately. You can then send the snapshot file, by way of SCP, to a remote system. The system prompts you for the destination server port, user ID, password, and the destination path to the remote directory.</p> <p>If you choose not to send the snapshot file to a remote system, the system saves the file locally. The next time you log in to the admin console, the System Snapshot tab contains a link to the snapshot file.</p>

Using the Serial Console to Roll Back to a Previous OS Version

You can use the admin console to roll back the configuration to a previous state. If the rollback option is not available in the admin console, you can use the procedure described in this section to perform the system rollback.

If you have not yet performed an OS service package upgrade, there is no previous state to roll back to, and the rollback option is not available. If you have performed an OS service package upgrade, any system and user configuration data created after the upgrade is lost unless you export the most current configuration files before rolling back the system and then import them afterwards.

To roll back to the previous OS service package:

1. Connect to the serial console.
2. In a browser window, sign in to the admin console.
3. Select **Maintenance > System > Platform**.

4. Click **Reboot Now** and then return to the console utility window. The window displays a message that the system is restarting.
5. After several moments, you are prompted to use the Tab key to select options. Press Tab, and when prompted for the configuration to load, type `rollback` and then press `Enter`.

After you click **Reboot Now**, the rollback status is output to the screen, and when complete, you are prompted to press Return (Enter) to modify system settings, which returns you to the initial setup options. When you are finished entering data, simply close the serial console window.

If you wait more than 5 seconds to enter your choice, the current system configuration is automatically loaded and you must go back to the admin console and click **Reboot Now** to start the process again. If you have already performed a system rollback, the rollback option is not available again until you upgrade the OS service package again.

Using the Serial Console to Reset the System to the Factory Image

In rare cases, you might need to reset the system to its original factory settings. Before performing this advanced system recovery option, contact PSGSC (<http://www.pulsesecure.net/support/>). If possible, export the most current system and user configuration data before performing a factory reset.

To perform a factory reset:

1. Connect to the serial console. In a browser window, sign in to the admin console.
2. Select **Maintenance > System > Platform**.
3. Click **Reboot** and then go back to the console utility window. The window displays a message that the system is restarting.
4. After several moments, you are prompted to use the Tab key to select options. Press Tab, and when prompted for the configuration to load, type `factory-reset` and then press `Enter`. If you wait more than 5 seconds to enter your choice, the current system configuration is automatically loaded, and you must go back to the admin console and click **Reboot Now** to start the process again.
5. When you are prompted to confirm performing a factory reset, type `proceed` and then press `Enter`. The system begins the process of resetting the machine to its original settings and outputs several screens of data. After several minutes, you are prompted to use the Tab key to select configuration choices.

When prompted to press the Tab key, do one of the following:

- Wait for the default selection (current) to start automatically.
- Press Tab, type current, and then press `Enter`.

You are then prompted to enter the initial configuration settings. For details on how to proceed, see the installation guide provided in the product packaging or on the Ivanti Global Support Center.

After you complete the initialization process, you can upgrade to the latest OS service package and import saved system and user configuration files to return to the last good working state of your system.

You might receive errors from the system during the initial setup or on a factory reset. Before the system starts services, it monitors the network port for a maximum of 120 seconds. The system checks the link status and sends ARP requests to the default gateway. If there is a problem, after 5 seconds, the system displays a message on the serial console that starts with NIC:..... If the link recovers within 120 seconds, the startup process continues. If the link does not recover, the following message is displayed:

Internal NIC:.....[Down code=0x1]

- **0x1** means that the interface link status reported by the NIC remains off (for example, a disconnected cable or a cable is in the wrong port).
- **0x2** means that the gateway is unreachable. The system boots but is not reachable from IP addresses bound to that network port.

Certificate Security Administration

Understanding Digital Certificate Security

Ivanti Policy Secure(IPS) uses Public Key Infrastructure (PKI) to secure the data sent to clients over the Internet. PKI is a security method that uses public and private keys to encrypt and decrypt information. These keys are enabled and stored through digital certificates. A digital certificate is an encrypted electronic file issued by a certificate authority (CA) that establishes credentials for client/server transactions.

In public key cryptography, a public/private key pair is used to encrypt and decrypt data. Data encrypted with a public key, which the owner makes available to the public, can be decrypted with the corresponding private key only, which the owner keeps secret and protected. For example, if User1 wants to send User2 an encrypted message, User1 can encrypt it with User2's public key and send it. User2 then decrypts the message with the private key. The reverse process is also useful: encrypting data with a private key and decrypting it with the corresponding public key. This process is known as creating a digital signature. For example, if User1 wants to present their identity as the sender of a message, they can encrypt the message with her private key and send the message to User2. User2 then decrypts the message with User1's public key, thus verifying that User1 is indeed the sender.

IPS uses the following types of digital certificates to establish credentials and secure session transactions:

- Device certificates—A device certificate helps to secure network traffic to and from the Ivanti service using elements such as company name, a copy of your company's public key, the digital signature of the CA that issued the certificate, a serial number, and expiration date. In addition, IPS uses a device certificate for communications with the Infranet Enforcers.
- Trusted client CAs—A trusted client CA is a client-side certificate issued by a CA. You can use trusted client CAs in the access management framework realm and role configurations to require certificates or certificates with specific attributes. For example, you may specify that users must present a valid client-side certificate with the OU attribute set to "yourcompany.com" to sign into the Users authentication realm.
- Trusted server CAs—A trusted server CA is the certificate of a Web server that you trust. You can install a trusted server CA to validate the credentials of the web sites that users access through the Ivanti Secure Access Client service.

- Code-signing certificates—A code-signing certificate (also called an applet certificate) is a type of server-side certificate that re-signs Java applets that are intermediated by IPS. You can use the self-signed code-signing certificate that comes pre-loaded, or you can install your own code-signing certificate.
- Client Authentication certificates—The client auth certificate is used when backend SSL servers require IPS to present a client certificate.

- The system can verify certificates that use SHA2 as the message digest.
 - Only ECDSA certificates are supported other DSA certificates are not supported.
-

Using Device Certificates

This topic describes how to use device certificates. It includes the following information:

Understanding Device Certificates

A device certificate helps to secure network traffic to and from the Ivanti Secure Access Client service using elements such as your company name, a copy of your company's public key, the digital signature of the Certificate Authority (CA) that issued the certificate, a serial number, and an expiration date. The system also uses device certificates for secure communications with the Infranet Enforcer.

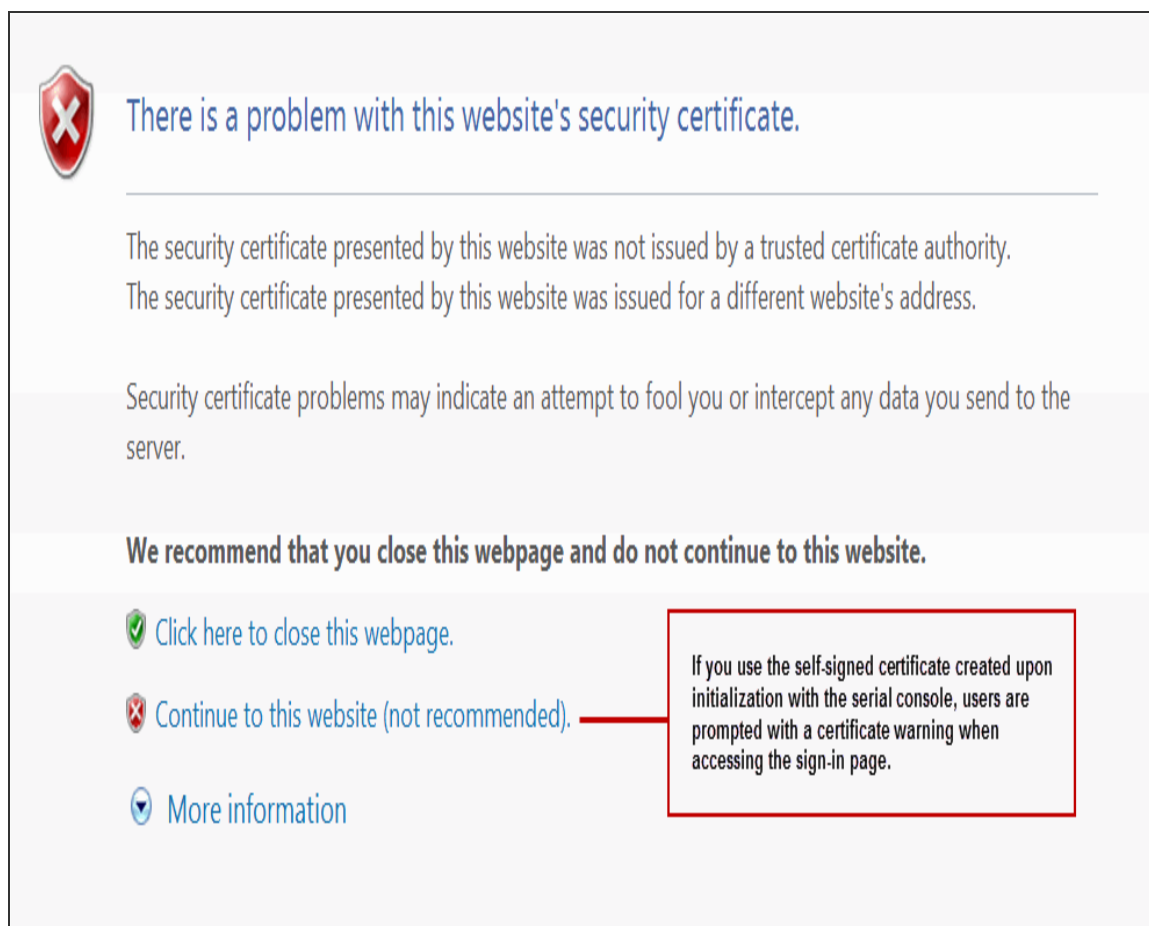

When receiving encrypted data from the system, the client's browser first verifies whether the device certificate is valid and whether the user trusts the CA that issued the certificate. If the user has not already indicated that they trust the certificate issuer, the Web browser prompts the user to accept or install the certificate.

The system supports X.509 device certificates in DER and PEM encode formats (file extensions include .cer, .crt, .der, and .pem) as well as PKCS #12 (file extensions include .pfx and .p12). The system also supports the following features:

- Intermediate device CA certificates—Within a certificate hierarchy, one or more intermediate certificates are branched off a single root certificate.
- Multiple device certificates—When using multiple device certificates, each certificate handles validation for a separate hostname or fully qualified domain name (FQDN) and can be issued by a different CA.

Understanding Self-Signed Certificates

When you initialize the system with the serial console, the system creates a self-signed certificate that enables you to immediately begin setting up the system. Users are prompted with a security alert each time they sign in because the certificate is not issued by a trusted CA.

Before promoting the system to production use, we recommend you replace the self-signed certificate with a certificate issued by a trusted CA.

In IPS deployments with ScreenOS Enforcers, you must use a CA-signed device certificate. If you use a self-signed certificate, the ScreenOS Enforcer does not allow a connection. Import a CA-signed device certificate into IPS, and then import the certificate of the CA that signed the device certificate into the ScreenOS Enforcer.

Importing a Device Certificate and Private Key

The system uses certificates to verify itself to other network devices. A digital certificate is an electronic means of verifying your identity through a trusted third party, known as a Certificate Authority (CA). Your company might use its own enterprise CA server, or it might use a reputable third-party CA.

To import an enterprise root server certificate and private key:

1. Select **System > Configuration > Device Certificates**.

Configuration > Certificates > Device Certificate

Device Certificate

[Licensing](#) [Security](#) [Certificates](#) [DMI Agent](#) [Client Types](#) [SAML](#) [Guest Access](#) [Mobile](#) [Client Configuration](#) [Advanced Networking](#) [Notification](#)

[Device Certificates](#) [Trusted Client CAs](#) [Trusted Server CAs](#) [Client Auth Certificates](#) [Certificates Validity Check](#)

Specify the Device Certificate(s). If you don't have a certificate yet, you can create a CSR and import the resulting signed certificate. If necessary, you can add custom [Intermediate CAs](#).

[Import Certificate & Key...](#) [Delete...](#)

10 records per page

	Certificate issued to	Issued by	Valid Dates
<input type="checkbox"/>	isa-hw54.ppsa.local	ppsqa-WIN2016SRV-CA-1	Aug 22 14:36:14 2022 GMT to Aug 21 14:36:14 2024 GMT

2. Click **Import Certificate & Key** to display the configuration page.

Configuration > Certificates > Import Certificate and Key

Import Certificate and Key

Use one of the forms below to import an existing certificate and its corresponding private key. If the files are encrypted, you will also need to specify the password.

▼ If certificate file includes private key

Certificate File: No file chosen

Password Key:

▼ If certificate and private key are separate files

Certificate File: No file chosen

Private Key File: No file chosen

Password Key:

▼ Import via System Configuration file

All Device Certificates and CSRs will be imported and added to the existing certificates and CSRs.

System Configuration File: No file chosen

Password:

3. Use one of the following options to complete the import procedure:

- **If certificate file includes private key**—When the certificate and key are contained in one file. The file format is .pfx.
- **If certificate and private key are separate files**—When the certificate and key are in separate files.
- **Import via System Configuration file**—When the certificate and key are contained in a system configuration file. With this option, the system imports all the certificates specified (including private keys and pending CSRs, but not the corresponding port mappings).

In the appropriate form, browse to the certificate and key files. If the file is encrypted, enter the password key.

4. Click **Import**.

The **Import Certificate** and **Key** button is disabled on FIPS hardware platforms because importing private keys is not allowed. On a FIPS hardware platform, you must create a CSR and then import a signed certificate from the CA.

Creating a Certificate Signing Request

If your company does not own a digital certificate for its Web servers, you can create a certificate signing request (CSR) and then send the request to a CA for processing. When you create a CSR, a private key is created locally that corresponds to the CSR. If you delete the CSR at any point, this file is also deleted, prohibiting you from installing a signed certificate generated from the CSR.

To create a certificate signing request:

1. Select **System > Configuration > Certificates > Device Certificates**.
2. Click **New CSR** to display the configuration page.
3. Complete the required information and click **Create CSR**.
4. Follow the onscreen instructions, which explain what information to send to the CA and how to send it.

When you submit a CSR to a CA authority, you might be asked to specify either the type of Web server on which the certificate was created or the type of Web server the certificate is for. Select apache (if more than one option with apache is available, select any). If you are prompted for the certificate format to download, select the standard format.

Do not send more than one CSR to a CA at one time. Doing so can result in duplicate charges.

Configuration > Certificates > New Certificate Signing Request

New Certificate Signing Request

Use this page to create a new Certificate Signing Request (CSR) to send to your Certificate Authority of choice.

Common Name:
(e.g., secure.company.com)

Organization Name:
(e.g., Company Inc.)

Org. Unit Name:
(e.g., IT Group)

Locality:
(e.g., SomeCity)

State (fully spelled out):
(e.g., California)

Country (2 letter code):
(i.e., US)

Email Address:

Key Type: ☒ RSA ☐ ECC

Key Length: bits

Please enter some random characters to augment the system's random key generator.
We recommend that you enter approximately twenty characters.

Random Data:
(used for key generation)

To view details of any pending requests that you previously submitted, click the Certificate Signing Request Details link.

Importing a Signed Certificate Created from a CSR

When you receive the signed certificate from the CA, import it.

To import a signed device certificate created from a CSR:

1. Select **System > Configuration > Certificates > Device Certificates**.
2. Under **Certificate Signing Requests**, click the **Pending CSR** link that corresponds to the signed certificate.

- Under Import signed certificate, browse and select the certificate file you received from the CA, and then click **Import**.

🔒 CSR created successfully: Your CSR was created successfully. See below for instructions on sending the CSR to a Certificate Authority. The certificate approval process may take several days. When you receive the signed certificate from the Certificate Authority, you will need to import the certificate to complete this process.

[Configuration](#) > Pending Certificate Signing Request

Pending Certificate Signing Request

CSR Details

[Back to Device Certificates](#)

Step 1. Send CSR to Certificate Authority for signing

To send the CSR to a Certificate Authority (CA), you need to copy the encoded text below, including the BEGIN and END lines, and submit it to the CA in one of the following ways:

- Save the text as a .cert file and attach it to an email message to the CA
- Paste the text into an email message to the CA
- Paste the text into a Web form provided by the CA

Note: Manage the CSR process carefully. If you submit more than one CSR to a CA, you may be billed for each CSR.

```
-----BEGIN CERTIFICATE REQUEST-----
MIIB8zCCAVwCAQAwdzELMAkGA1UEBhMCZ8xZAJBgNVBAsMAj8/
MQswCQYDVQQH
DAIPzEUMBIGA1UECgwLUHVsc2VTZW1cmUxZAJBgNVBAsMAj8/
MREwDwYJKoZI
```

Step 2. Import signed certificate

When you receive the signed certificate file from the CA, select it below and click Import. This will add the signed certificate and remove this pending CSR.

Signed certificate: No file chosen

Understanding Intermediate Certificates

Within a certificate hierarchy, one or more intermediate certificates are branched off a single root certificate. The root certificate is issued by a root CA and is self-signed. Each intermediate certificate is issued by the certificate preceding it in the chain.

To use chained certificates in your deployment, you must ensure that the server and client (Web browser) together contain the entire certificate chain. For example, you can secure traffic using a chain that stems from a VeriSign root certificate. If your users' browsers come preloaded with VeriSign root certificates, you need to install only the lower-level certificates in the chain. When your users sign in, the system presents any required certificates within the chain to the browser to secure the transaction. The system creates the proper links in the chain using the root certificate's IssuerDN. If the system and browser together do not contain the entire chain, the user's browser does not recognize or trust the device certificate because it is issued by another certificate instead of by a trusted CA.

You can upload one or more intermediate CAs in a PEM file. The entire chain must be sent to the client in descending order, starting with the root certificate.

Within a certificate hierarchy, one or more intermediate certificates are branched off a single root certificate. The root certificate is issued by a root CA and is self-signed. Each intermediate certificate is issued by the certificate preceding it in the chain.

To use chained certificates in your deployment, you must install the appropriate client-side certificates in each user's Web browser and then upload the corresponding CA certificates to Ivanti Secure Access Client Service Intermediate CA store. Use one of the following methods to upload the certificate chain:

1. Import the entire certificate chain in one file. The file must contain the root certificate and any subcertificates whose parents are in the file or already imported. You can include certificates in any order in the import file.
2. Import the certificates one at a time in descending order. You must install the root certificate first, and then install the remaining chained certificates in descending order.

If you follow one of these methods, the system automatically chains the certificates together in the correct order and displays them hierarchically in the admin console.

If you install multiple certificates in a user's Web browser, the browser prompts the user to choose which certificate to use when signing in.

Importing Intermediate CA Certificates

To import an intermediate CA certificate:

1. Select **System > Configuration > Certificates > Device Certificates**.
2. Click the **Intermediate Device CAs** link to display the management page.

3. Click **Import CA certificate**
4. Browse to the certificate file, select it, and click **Import Certificate** to complete the import operation.

Importing a Renewed Certificate That Uses the Existing Private Key

You can renew a device certificate in two ways:

- **Submit a new CSR to a CA**—This process is more secure because the CA generates a new certificate and private key and retires the older private key. To use this renewal method, you must first create a CSR through the admin console.
- **Request renewal based on the CSR previously submitted to the CA**—This process is less secure, because the CA generates a certificate that uses the existing private key.

When you order a renewed certificate, you must either resubmit your original CSR or ensure that the CA has a record of the CSR that you submitted for your current certificate.

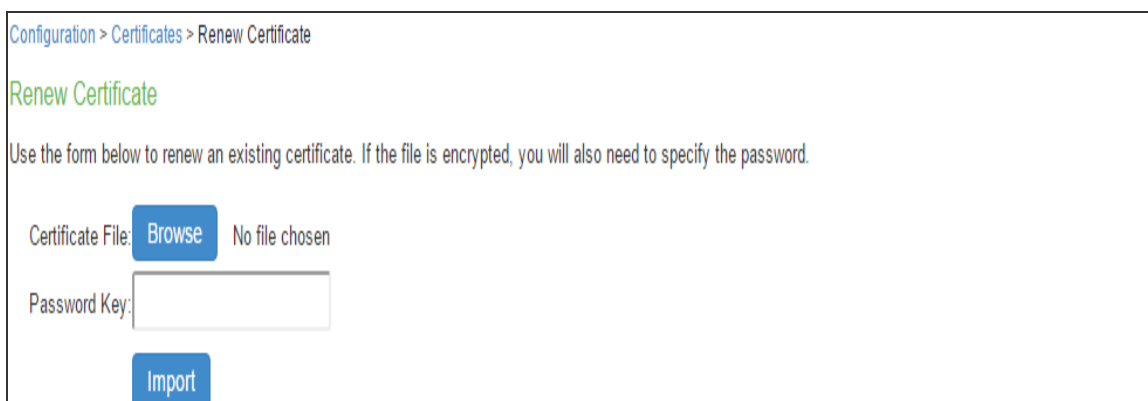

To import a renewed device certificate that uses the existing private key:

Follow your CA's instructions for renewing a certificate that you previously purchased through them. Be sure to specify the same information you used in the original CSR. Your CA uses this information to create a new certificate that corresponds to the existing key.

Even though you specify the same information used in the original CSR, your root CA might have different serial numbers and keys from the original. You might need to support both new client and old client certificates during the transition period, which also requires that you maintain two root CA certificates (your existing certificate and the renewed certificate), at least temporarily

1. Select **System > Configuration > Certificates > Device Certificates**.
2. Click the link that corresponds to the certificate you want to renew.
3. Click **Renew Certificate** to display the page.
4. In the Renew the Certificate form, browse to the renewed certificate file, enter the password for the certificate key, and click **Import**.

The screenshot shows a web interface for renewing a certificate. At the top, a breadcrumb trail reads 'Configuration > Certificates > Renew Certificate'. Below this, the title 'Renew Certificate' is displayed in green. A descriptive text states: 'Use the form below to renew an existing certificate. If the file is encrypted, you will also need to specify the password.' The form contains two main input areas: 'Certificate File:' with a blue 'Browse' button and the text 'No file chosen', and 'Password Key:' with an empty text box. At the bottom of the form is a blue 'Import' button.

Downloading a Device Certificate

You download the device certificate to your local host so that you can import it into other network devices as needed.

To download a device certificate:

1. Select **System > Configuration > Certificates > Device Certificates**.
2. Click the link of the device certificate you want to download to display the configuration page.
3. Click the **Download** link.
4. Save the file to the desired location.

Using Device Certificates with Virtual Ports

Virtual ports can be used to create multiple fully qualified domain names for user sign-in.

When a user tries to sign in using the IP address defined in a virtual port, the system uses the certificate associated with the virtual port to initiate the SSL transaction and for NetScreen Address Change Notification (NACN) communications with the Infranet Enforcer.

You must associate the signed certificate with the port that is connected to the Infranet Enforcer. You can use the same port and certificate for Ivanti Secure Access Client.

You can implement digital certificate security with virtual ports in either of the following ways:

- **Associate all hostnames with a single certificate**—With this method, you use a single wildcard certificate to validate the identity of all system hostnames, regardless of which hostname is used to sign into. A wildcard certificate includes a variable element in the domain name, making it possible for users who sign in from multiple hosts to map to the “same” domain. For example, if you create a wildcard certificate for *.yourcompany.com, the system uses the same certificate to validate its identity to users who sign in to employees.yourcompany.com as it does to users who sign into partners.yourcompany.com.
- **Associate each hostname with its own certificate**—With this method, you associate different hostnames with different certificates. Create a virtual port for each hostname. A virtual port activates an IP alias on a physical port. For example, you can create two virtual ports on a single appliance, mapping the first virtual port to the IP address 10.10.10.1 (sales.yourcompany.com) and the second virtual port to the IP address 10.10.10.2 (partners.yourcompany.com). Then you can associate each of these virtual ports with its own certificate, ensuring that users authenticate through different certificates.

To associate certificates with virtual ports:

- Create the virtual ports.
- Import the device certificates.
- Associate the device certificates with the virtual ports:
 1. Select **System > Configuration > Certificates > Device Certificates**.
 2. Click the link of the device certificate you want to configure to display the configuration page.
 3. Use the controls in the “Present certificate on these ports” section to associate ports with the certificate.

You can assign only one device certificate to the Management Port. If you assign a certificate other than the default device certificate to the Management Port, the default device certificate is automatically deselected as the default. If you do not select a device certificate for the Management Port, the system uses the default device certificate that is presented on the Internal port. You cannot assign certificates to Management Port VIPs.

Enabling Certificate Revocation Check for Device Certificate

To enable the CRL for Device Certificates:

1. Go to **System > Configuration > Certificates > Device Certificates**.
2. Click on the certificate from the list to go to the certificate details.
3. In the Certificate Details page, go to **Certificate Status Checking** and enable the **Use CRLs (Certificate Revocation Lists)** checkbox.

▼ Certificate status checking

☒ Use CRLs (Certificate Revocation Lists)

Using Trusted Client CAs

This topic describes how to use trusted client Certificate Authorities (CAs).

Understanding Trusted Client CAs

A trusted client CA is a CA that you deem trusted by adding it to the trusted client CA store. The system trusts any certificate issued by that CA. To use client CA certificates, you must install and enable the proper certificates. Additionally, you must install the corresponding client-side certificates in your users' Web browsers, or you must use the MMC snap-in in your users' computer accounts (machine certificate). When validating a client-side CA certificate, the system verifies that the certificate is not expired or corrupt and that the certificate is signed by a CA that the system has been configured to recognize. If the CA certificate is chained, the system also follows the chain of issuers until it reaches the root CA, validating each issuer in turn. The system supports X.509 CA certificates in DER and PEM encode formats.

When you install a client-side certificate, you must determine whether to use the certificate to identify individual users or individual machines. To use the certificate to identify individual users, you must install the certificate in each user's individual certificate store. Then you must enable authentication using a certificate server, or you must enable authorization using realm, role, and/or resource policy settings. To use the certificate to identify individual machines, you must install the certificate in each computer's certificate store. Then you must configure a Host Checker policy that checks for the machine certificate and authorizes access to realms, roles, or resource policies based on the certificate's validity.

The system supports using the following additional features with CA certificates:

- **Certificate servers**—A certificate server is a type of local authentication server that allows you to authenticate users based solely on their certificate attributes rather than authenticating them against a standard authentication server (such as LDAP or RADIUS), and it requires specific certificates or certificate attributes.
- **Certificate hierarchies**—Within a certificate hierarchy, one or more subordinate certificates (called intermediate certificates) are branched off a root certificate to create a certificate chain. Each intermediate certificate (also called a chained certificate) handles requests for a part of the root CA domain. For example, you can create a root certificate that handles all requests to the yourcompany.com domain and then branch off intermediate certificates that handle requests to partners.yourcompany.com and employees.yourcompany.com. When you install a chained certificate, the system confirms that the chain is valid and allows users to authenticate using the leaf certificate (that is, the lowest certificate in the chain).

- **Certificate revocation lists**—Certificate revocation is a mechanism by which a CA invalidates a certificate before its expiration date. The CA publishes a certificate revocation list (CRL) which is a list of revoked certificates. Within CRLs, each entry contains the serial number of the revoked certificate, the date that the certificate was revoked, and the reason the certificate was revoked. The CA can invalidate a certificate for various reasons such as when the employee to whom the certificate is issued leaves the company, the certificate's private key is compromised, or the client-side certificate is lost or stolen. When the CA revokes a certificate, the system can appropriately deny access to users who present a revoked certificate.

Trusted Client CA Implementation Notes

Uploading a trusted client CA certificate does not enable client-side SSL authentication or authorization. To do so, you must use a certificate server, or enable certificate restrictions at the realm, role, or resource policy level, or create a Host Checker policy that verifies a machine certificate.

With client-side certificates, we strongly recommend that you advise users to close their Web browsers after signing out. If they do not, other users might be able to use their open browser sessions to access certificate-protected resources without reauthentication. After loading a client-side certificate, Internet Explorer caches the certificate's credentials and private key. The browser keeps this information cached until the user closes the browser (or, in some cases, until the user reboots the workstation). For details, see <http://support.microsoft.com/?kbid=290345>.) To remind users to close their browsers, you can modify the sign out message on the Sign-in Pages tab.

Certificate authentication does not work on Internet Explorer 8 and 9 if SSL 2.0 is enabled with other SSL and TLS versions. For details, see <http://support.microsoft.com/kb/2851628>.

Understanding CRLs

A certificate revocation list (CRL) is a mechanism for canceling a client-side certificate. As the name implies, a CRL is a list of revoked certificates published by a CA or a delegated CRL issuer. The system supports base CRLs, which includes the company's revoked certificates in a single, unified list.

The system determines the correct CRL to use by checking the client's certificate. (When it issues a certificate, the CA includes CRL information for the certificate in the certificate itself.) To ensure that it receives the most up-to-date CRL information, the system periodically contacts a CRL distribution point to get an updated list of CRLs. A CRL distribution point (CDP) is a location on an LDAP directory server or Web server where a CA publishes CRLs. The system downloads CRL information from the CDP at the interval specified in the CRL, at the interval that you specify during CRL configuration, and when you manually download the CRL. The system also supports CRL partitioning. CRL partitioning enables you to verify portions of very large CRLs without spending the time and bandwidth necessary to access and validate a very large CRL or collection of large CRLs. CRL partitioning is only enabled when you employ the Specify the CDP(s) in the client certificates method (described below). In this case, the system validates the user by verifying only the CRL specified in the client certificate.

Although CAs include CRL information in client-side certificates, they do not always include CDP information as well. A CA can use any of the following methods to notify the system of a certificate's CDP location:

- **Specify the CDP(s) in the CA certificate**—When the CA issues a CA certificate, it might include an attribute specifying the location of the CDPs that the system should contact. If more than one CDP is specified, the system chooses the first one listed in the certificate and then fails over to subsequent CDPs, if necessary.
- **Specify the CDP(s) in the client certificates**—When the CA issues a client-side certificate, it might include an attribute specifying the location of the CDPs that the system must contact. If more than one CDP is specified, it chooses the first one listed in the certificate and then fails over to subsequent CDPs, if necessary. When the system employs CRL partitioning and the client certificate specifies only one CRL, it performs verification using only that CRL.

If you choose this method, the user receives an error on the first sign-in attempt because no CRL information is available. Once the system recognizes the client's certificate and extracts the CRL location, it can start downloading the CRL and subsequently validate the user's certificate. To successfully sign in, the user must try to reconnect after a few seconds.

- **Require the administrator to manually enter the CDP location**—If the CA does not include the CDP location in the client or CA certificates, you must manually specify how to download the entire CRL object. You can specify a primary and backup CDP. (Manually entering the CDP location provides the greatest flexibility because you do not need to reissue certificates if you change the CDP location.)

The system compares the user's certificate against the appropriate CRL during authentication. If it determines that the user's certificate is valid, the system caches the certificate attributes and applies them, if necessary, during role and resource policy checks. If it determines that the user's certificate is invalid, if it cannot contact the appropriate CRL, or if the CRL is expired, it denies the user access.

- The system supports only CRLs that are in a PEM or DER format and that are signed by the CA for which the revocations apply.
 - The system only saves the first CRL in a PEM file.
-

Understanding OCSP

The Online Certification Status Protocol (OCSP) is a service that enables you to verify client certificates. When OCSP is enabled, the system becomes a client of an OCSP responder and forwards validation requests for users based on client certificates. The OCSP responder maintains a store of CA-published certificate revocation lists (CRLs) and maintains an up-to-date list of valid and invalid client certificates. After the OCSP responder receives a validation request, it validates the status of the certificate using its own authentication database, or it calls upon the OCSP responder that originally issued the certificate to validate the request. After formulating a response, the OCSP responder returns the signed response, and the original certificate is either approved or rejected.

Importing a Trusted Client CA Certificate

If you require users to provide a client-side certificate to sign in, you must upload the corresponding CA certificate. You can upload CA certificates manually, or you can configure the system to upload CA certificates automatically. The system uses the uploaded certificate to verify that the browser-submitted certificate is valid. In addition, you can specify if you want to automatically import CA certificates for validation, and you can specify a CRL or OCSP retrieval method to use to automatically import CA certificates.

To import a trusted client CA certificate:

1. Select **System > Configuration > Certificates > Trusted Client CAs** to display the configuration page.
2. Click **Import CA Certificate** to display the configuration page.
3. Browse to the certificate file, select it, and click **Import Certificate** to complete the import operation.

Renewing a Certificate

To renew a certificate:

1. Select **System > Configuration > Certificates > Trusted Client CAs**.
2. Click the link for the certificate you want to renew.
3. Click **Renew Certificate** to display the import certificate page.
4. Browse to the certificate file, select it, and click **Import Certificate** to complete the import operation.

Configuring Auto-Importing of Client Certificates

To enable auto-importing:

1. Select **System > Configuration > Certificates > Trusted Client CAs**.
2. Click the **Auto-Import Options** button to display the options.
3. Complete the configuration described in table.
4. Save your changes.

Settings	Guidelines
Auto-import trusted CAs	Select this option to enable auto-import and display its configuration settings.
Client Certificate Status Checking	Select a method to validate the trusted client certificate: <ul style="list-style-type: none">• None—Do not validate.• Use OCSP—Use the OCSP method, validating the client certificate in real-time, as needed. After you select this option, you can specify options for OCSP.• Use CRLs—Use CRLs to validate the client certificate. After you select this option, you can specify options for OCSP.

Settings	Guidelines
	<ul style="list-style-type: none">• Use OCSP with CRL fallback—Use the OCSP validation method when possible, but attempt to validate client certificates using CRLs if the OCSP method fails (for example, if the link to the OCSP responder fails). After you select this option, you can specify options for OCSP.• Inherit from root CA—Use the method configured for the device certificate.
CDP(s)/OCSP responder	Select the location of the responder value: <ul style="list-style-type: none">• None—Do not use the responder.• From client certificate—Use the responder value configured in the client certificate.• From trusted CA certificate—Use the responder value configured in the trusted CA certificate that has been uploaded to the system.
Verify imported CA certificates	Select this option to verify that this trusted client CA is valid. Enabling this will check the CRL of this certificate's issuer, and repeat up the chain until reaching the root trusted client CA.
Skip Revocation check when OCSP/CDP server is not available	Select this option to instruct IPS to skip revocation check and accept end user certificates when either OCSP server or CDP server is not accessible over the network. This option is applicable to digital certificates used for end user authentication. IPS skips the revocation check in the following conditions: <ul style="list-style-type: none">• Server IP is not reachable• Server Hostname is either not resolvable or resolving to non OCSP/CRL Server IP• Proxy IP is either not reachable or not resolving• Download CRL has expired• OCSP/CRL service in Server is not responding

Configuring Options for Trusted Client CA Certificates

To configure options for the trusted client CA certificate:

1. Select **System > Configuration > Certificates > Trusted Client CAs**.
2. Under **Port Selection for CRL** and **OCSP Download**, select the port: Internal Port, External Port, or Management Port.

Configuration > Certificates > Trusted Client CAs

Trusted Client CAs

Configuration

Save

Users can be required to present valid client-side certificates to sign in (see the realm-specific [Certificate Authentication Policy](#) page). Specify trusted certificate authorities.

Auto-import options... **Proxy Settings...** **Import CA Certificate...** **Delete...**

10 records per page

	Trusted Client CA	Trusted for client authentication?	Valid dates	Status checking
<input type="checkbox"/>	 ppsga-WIN2016SRV-CA-1	Yes	2018/07/31 - 2028/07/31	None

3. Click the certificate you want to configure.

4. Complete the configuration described in the following table.

Settings	Guidelines
Certificate	<p>Use the expander buttons to display the following details:</p> <ul style="list-style-type: none">• Issued To—Name and attributes of the entity to whom the certificate is issued.• Issued By—Name and attributes of the entity that issued the certificate. Note that the value of this field must match either the Issued To field (for root certificates) or the Issued To field of the next highest certificate in the chain (for intermediate certificates).• Valid Dates—Time range for which the certificate is valid.• Details—Various certificate details, including its version, serial number, signature algorithm, CRL distribution points, public key algorithm type, and public key.
Client Certificate Status Checking	<p>Select a method to validate the trusted client certificate:</p> <ul style="list-style-type: none">• None—Do not validate.• Use OCSP—Use the OCSP method, validating the client certificate in real-time, as needed. After you have selected this option and saved the configuration, you can specify options for OCSP.• Use CRLs—Use CRLs to validate the client certificate. After you have selected this option and saved the configuration, you can specify options for CRL.• Use OCSP with CRL fallback—Use the OCSP validation method when possible, but attempt to validate client certificates using CRLs if the OCSP method fails (for example, if the link to the OCSP responder fails). After you have selected this option and saved the configuration, can specify options for OCSP and CRL.

Settings	Guidelines
Verify Trusted Client CA	Select this option to verify that this trusted client CA is valid. Enabling this will check the CRL of this certificate's issuer, and repeat up the chain until reaching the root trusted client CA.
Trusted for Client Authentication	Clear this check box to exclude the CA from being trusted for client certificate authentication. You might want to do this if this CA was added for another trusting purpose, such as SAML signature verification or machine certificate validation.
Skip Revocation check when OCSP/CDP server is not available	<p>Select this option to instruct IPS to skip revocation check and accept end user certificates when either OCSP server or CDP server is not accessible over the network. This option is applicable to digital certificates used for end user authentication.</p> <p>IPS skips the revocation check in the following conditions:</p> <ul style="list-style-type: none">• Server IP is not reachable• Server Hostname is either not resolvable or resolving to non OCSP/CRL Server IP• Proxy IP is either not reachable or not resolving• Download CRL has expired• OCSP/CRL service in Server is not responding

5. Save your changes.
6. If you have enabled CRL Checking, click **CRL Checking Options**.

7. If you have enabled OCSP options:

- Click **OCSP** Options.
- Complete the configuration described in the following table.

Settings	Guidelines
Use	<p>Select the type of OCSP responder to validate trusted client CAs:</p> <p>None—The system does not use OCSP to verify the status of certificates issued by this CA.</p> <p>Responder(s) specified in the CA certificate—The system uses OCSP responders specified in the imported client CA to perform verification. When you select this option, the system displays a list of OCSP responders specified in the imported CA (if any) and the last time they were used.</p> <p>Responder(s) specified in the client certificates—The system uses responders specified during client authentication to perform verification. When you select this option, the system displays a list of known OCSP responders (if any) and the last time they were used.</p> <p>Manually configured responders—The system uses primary and secondary OCSP responders at the addresses you specify.</p>
Device Certificate to sign the request	Select the appropriate device certificate or leave the default (unsigned).
Signature Hash Algorithm	Select SHA-1 or SHA-2.
Use Nonce	A nonce is random data the system includes in an OCSP request and the OCSP responder returns in the OCSP response. The system compares the nonce in the request and response to ensure that the response is generated by the OCSP responder. If the two do not match, the system disregards the response and sends a new request.

8. Save the configuration.

9. After you have added an OCSP responder to the list, you can click its link to display the page.

10. Complete the configuration described in the following table.

Settings	Guidelines
Responder Signer Certificate	Browse to the network path or local directory location of a Responder Signer Certificate. This is the certificate the OCSP responder uses to sign the response. You must specify the Responder Signer Certificate if the signer certificate is not included in the response.
Trust Responder Certificate	Select this option to allow an OCSP responder certificate that matches the responder signer certificate.
Revocation Checking	Select this option to ensure that the certificate has not recently been revoked. This option has implications only if you specified the Use OCSP with CRL fallback option.
Allow clock discrepancy	Use this option to account for possible mismatches in timestamps between the system clock and the OCSP responder clock. If the mismatch is significant, the system disregards the response from the OCSP responder as out of date or expired.

11. Save the configuration.

Configuring a Proxy Server for CRL Downloads and OCSP Status Checks

You can configure the system to send CRL download requests and OCSP status checks to the proxy server and collect the response. You might want to do this if you deploy proxy server to control access to the Internet.

The following types of CRL downloads can use the proxy server:

- CRL distribution points (CDPs) specified in the trusted client CAs
- CDPs specified in client certificates
- Manually configured CDPs

Similarly, the system can send OCSP requests to the OCSP responder through the proxy server. The OCSP responses are also received through the proxy server. This feature is useful when you deploy many IPS systems and the OCSP responders are located outside the network.

To configure a proxy server:

1. Select **System > Configuration > Certificates > Trusted Client CAs**.
2. Click **Proxy Settings** to display the page.
3. Complete the configuration described in the following table.
4. Save the configuration.

Settings	Guidelines
Use Proxy Server for HTTP-based CRL download	Select to enable the CRL operations to use a proxy server.  You can configure a proxy server for web-based URLs, not LDAP URLs.
Use Proxy Server for HTTP-based OCSP status checking	Select to enable the OCSP operations to use a proxy server.
Host Address	Specify either an IP address or a fully qualified domain name.
Port	Enter the proxy server port number if it is different from the default value of 80.
Username/password	If your proxy server required authentication, enter a username and password to log in to the proxy server.

Using Client Auth Certificates

This topic describes how to use client auth certificates.

Understanding Client Auth Certificates

In certain corporate environments, servers on the LAN are protected with two-way SSL authentication. These servers require the client to authenticate by presenting a valid certificate.

In the remote access scenario, ICS is a client of these servers. You can configure IPS to present client authentication certificates to servers whenever it communicates over SSL.

This feature authenticates end users or end-user machines to servers on the corporate LAN.

The SSL protocol provides for mutual authentication of server and client at the time of session initiation. The client part of the authentication is optional. For enhanced security, some deployments may require that the client also authenticate itself with a certificate. Normally, when setting up an SSL connection with a server on behalf of the end user, ICS does not present any certificate to the server. It needs to be explicitly configured to present such certificate. This section explains how such configuration may be performed.

The basic idea is to upload a certificate, private key pair to the access management framework, and configure a mapping between this pair and a server resource. Subsequently, when an end user attempts to establish a connection with that server, IPS presents the associated certificate to the server. If no certificate is associated with the server in ICS certificate store, then it is assumed that the server does not demand client certificate.

If, during the SSL handshake, the back-end server requests a client certificate but IPS doesn't send a certificate, the end user sees an "access denied" error message. Similarly, if the back-end server rejects the IPS certificate, the end user sees an "access denied" error message. If a certificate is configured, is successfully retrieved and no error is encountered during handshake, the user is granted access to the server.

The IPS access management framework allows client authentication certificates to be uploaded to the device in two ways: generate a CSR and upload the signed certificate returned by the CA, or directly import the certificate if one is available.

Importing a Client Auth Certificate

The access management framework allows certificates that include the private key and for instances where the private key is in a separate file from the certificate. In addition, if your certificates have been exported into a system configuration file, you can import the system configuration file to upload the certificates.

To import the client auth certificates files:

1. Select **System > Configuration > Certificates > Client Auth Certificates**.
2. Click **Import Certificate & Key** to display the configuration page.

3. Complete the configuration described in table.
4. Click **Import**.

Settings	Guidelines
If certificate file includes private key	
Certificate File	Browse to the network path or local directory location of your private key file.
Password Key	Enter the password key.
If certificate and private file are separate keys	
Certificate File	Browse to the network path or local directory location of your certificate key file.
Private Key File	Browse to the network path or local directory location of your private key file.
Password Key	Enter the password key.
Import via System Configuration file	
System Configuration File	Browse to the network path or local directory location of the system configuration file.
Password	Enter the password.

Renewing a Client Auth Certificate

To renew a certificate:

1. Select **System > Configuration > Certificates > Client Auth Certificates**.
2. Click the link that corresponds to the certificate you want to renew.
3. Click **Renew Certificate** to display the configuration page.
4. In the **Renew the Certificate** form, browse to the renewed certificate file, enter the password for the certificate key, and click **Import**.

Configuring Two-Way SSL Authentication

To configure two-way SSL authentication:

1. Import the certificates used for two-way SSL handshake in the **System > Configuration > Certificates > Client Auth Certificates** window.
2. Define the back-end resource and assign a certificate to be presented when accessing it using the **Users > Resource Policies > Web > Client Authentication** window.

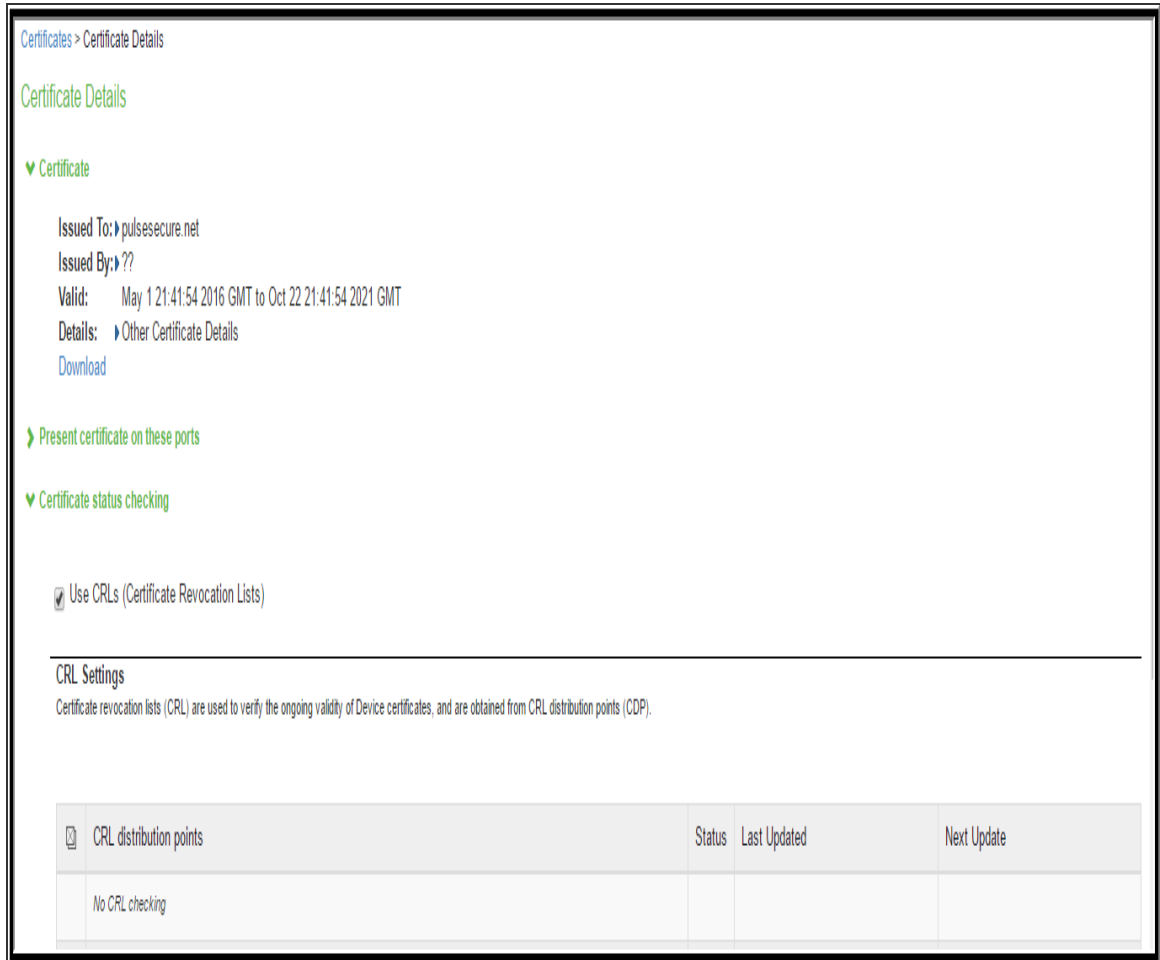

Enabling Certificate Revocation Check for Client Auth Certificate

Client Auth Certificate Revocation Check is only applicable for TLS Syslog Backend Server. It is not applicable for any other backend server configured to ask Client Certificate.

To enable the CRL for Client Auth Certificate:

1. Go to **System > Configuration > Certificates > Client Auth Certificates**.
2. Click on the certificate from the list to go to the certificate details.

3. In the Certificate Details page, go to **Certificate Status Checking** and enable the Use CRLs (Certificate Revocation Lists) checkbox.

The screenshot shows the 'Certificate Details' page. Under the 'Certificate status checking' section, the checkbox 'Use CRLs (Certificate Revocation Lists)' is checked. Below this is a section titled 'CRL Settings' with a description: 'Certificate revocation lists (CRL) are used to verify the ongoing validity of Device certificates, and are obtained from CRL distribution points (CDP)'. At the bottom, there is a table with columns for 'CRL distribution points', 'Status', 'Last Updated', and 'Next Update'. The table currently shows 'No CRL checking'.

CRL distribution points	Status	Last Updated	Next Update
No CRL checking			

4. Click on **Save Changes**.
5. Import the CA or CA Chain that issued the Client Auth Certificate to **System > Configuration > Trusted Client CAs**.
6. Once the CRL is successfully downloaded for Client Auth Certificate, it is listed in the CRL distribution points.

Certificate status checking

☒ Use CRLs (Certificate Revocation Lists)

Note: This option only applies to the Syslog Server.

CRL Settings

Certificate revocation lists (CRL) are used to verify the ongoing validity of Client Authentication certificates, and are obtained from CRL distribution points (CDP).

 CRL distribution points	Status	Last Updated	Next Update
 http://win-kurshgmdcp0.chibdc.test.sagacertserv.com/CertEnrollEnterpriseSub-CA.crl Last result: Success, same CRL	Enabled; OK: 2KB, 6 revocations	2016/06/08 13:19:57	2016/06/13 05:49:05

This version of the IPS supports the 3072 bit key length for Client Auth Certificates.

Configuration > Certificates > New Certificate Signing Request

New Certificate Signing Request

Use this page to create a new Certificate Signing Request (CSR) to send to your Certificate Authority of choice.

Common Name:
(e.g., secure.company.com)

Organization Name:
(e.g., Company Inc.)

Org. Unit Name:
(e.g., IT Group)

Locality:
(e.g., SomeCity)

State (fully spelled out):
(e.g., California)

Country (2 letter code):
(i.e., US)

Email Address:

Key Type: ☒ RSA ☐ ECC

Key Length: bits

Please enter some random characters in the box below the system's random key generator.
We recommend that you enter approximately twenty characters.

Random Data:
(used for key generation)

CRL Download for Device Certificate and Client Auth Certificate using LDAP based URL won't work due to dependency of LDAP Username and Password. In some cases, CDP LDAP URL hostname field is also required which is also not supported.

Using Trusted Server CAs

This topic describes trusted server certificate authorities (CAs).

Understanding Trusted Server CAs

All the trusted root CAs for the Web certificates installed in Internet Explorer are preinstalled. You might need to install a trusted server CA for additional Web servers in the following situations:

- If you are using third-party integrity measurement verifiers (IMVs) that are installed on a remote server, you must upload the trusted root certificate of the CA that signed the remote server's server certificate.
- If you are using virus signature version monitoring with your own staging site for storing the current virus signatures list, you must upload the trusted root certificate of the CA that signed the staging server certificate.
- You can install the trusted root CA certificate on the endpoint in any of the following ways:
- Use a CA certificate that is chained to a root certificate that is already installed on the endpoint, such as VeriSign.
- Upload the CA certificate and any intermediate CA certificates to the Ivanti Secure Access Client system. During client installation, the system automatically installs the trusted root device CA certificates on the endpoint. When prompted during installation, the user must allow the installation of the CA certificate(s).
- Prompt users to import the CA certificates on the endpoint using Internet Explorer or other Microsoft Windows tools. In other words, you can use common methods organizations use to distribute root certificates.

You cannot use CRL revocation checks for trusted server CA certificates.

Uploading Trusted Server CA Certificates

You can use the Trusted Server CAs page to upload the trusted root certificate of the CA that signed the Ivanti Secure Access Client service device certificate. If you upload a certificate chain, you must install the certificates one at a time in descending order starting with the root certificate (DER or PEM files), or you must upload a single file that contains the entire certificate chain (PEM files only). The system supports X.509 CA certificates in PEM (Base 64) and DER (binary) encode formats.

To upload CA certificates:

1. Select **System > Configuration > Certificates > Trusted Server CAs** to display the page.
2. Click **Import Trusted Server CA** to display the page.
3. Browse to the certificate file, select it, and click **Import Certificate** to complete the import operation.

Restoring the Prepopulated Group of Trusted Server CA Certificates

The **System > Configuration > Certificates > Trusted Server CAs** page is prepopulated with some of the trusted root CAs for the Web certificates installed in Internet Explorer and Windows. You can use the delete functionality on this page to delete CAs and the reset functionality to restore the list to the set that was installed during the upgrade. The reset operation clears all manually imported certificates.

To restore the prepopulated group of trusted CA certificates:

1. Select **System > Configuration > Certificates > Trusted Server CAs**.
2. Click **Reset Trusted Server CAs**.
3. Confirm that you want to restore the set of trusted server CAs that was installed when you upgraded.

Renewing a Trusted Server CA Certificate

If a trusted CA renews its certificate, you must upload the renewed CA certificate.

To import a renewed CA certificate:

1. Select **System > Configuration > Certificates > Trusted Server CAs**.
2. Click the link that corresponds to the certificate that you want to renew to display the page.
3. Click **Renew Certificate**.
4. Browse to the certificate file, select it, and click **Import Certificate** to complete the import operation.

Deleting a Trusted Server CA Certificate

You can delete any trusted server CA certificate, including preinstalled certificates.

To delete a trusted server CA certificate:

1. Select **System > Configuration > Certificates > Trusted Server CAs**.
2. Select the check box for the certificate you want to delete.
3. Click **Delete**, and then confirm that you want to delete the certificate.

Understanding ECC Certificates

Public-key cryptography is a cryptographic system that requires a secret key and a public key that are mathematically linked with each other. One key encrypts the plain text while the other decrypts the cipher text. RSA is the most widely used public-key algorithm.

Elliptic Curve Cryptography (ECC) were introduced as an alternative to RSA in public key cryptography. One advantage of ECC over RSA is key size versus strength. For example, a security strength of 80 bits can be achieved through an ECC key size of 160 bits, whereas RSA requires a key size of 1024. With a 112-bit strength, the ECC key size is 224 bits and the RSA key size is 2048 bits.

The most popular signature scheme that uses elliptic curves is called the Elliptic Curve Digital Signature Algorithm (ECDSA). The most popular key agreement scheme is called Elliptic Curve Diffie-Hellman (ECDH). An ECDH exchange is a variant of the Diffie-Hellman (DH) protocol and is an integral part of the Suite B cryptography standards proposed by the National Security Agency (NSA) for protecting both classified and unclassified information.

About Suite B

The Advanced Encryption Standard (AES) is a specification for the encryption of electronic data established by the U.S. National Institute of Standards and Technology (NIST) in 2001. Because a single encryption algorithm cannot satisfy all the needs of the national security community, NSA created a larger set of cryptographic algorithms, called Suite B, which can be used along with AES in systems used by national security users. In addition to AES, Suite B includes cryptographic algorithms for hashing, digital signatures, and key exchanges.

Per RFC 6460, to be Suite B TLS 1.2 compliant the server and client should negotiate with the following ciphers:

- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384

RFC 6460 also lists a transitional Suite B profile for TLS 1.0 and TLS 1.1. Clients and servers that do not yet support Suite B TLS 1.2 should negotiate with the following ciphers:

- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA

There is no special configuration to ensure that IPS negotiates Suite B ciphers. However, the following general steps should be performed to enable Suite B compliance:

- An ECC certificate signed by an ECC Root CA is associated with a network port.
- A P-256 CSR is signed by either a P-256 or P-384 Root CA.
- A P-384 CSR is signed by a P-384 Root CA.
- Manually enable only AES128 and/or AES256 custom ciphers.

IPS cannot be configured to allow only Suite B ciphers.

Using ECC Certificates

ECC certificates are currently supported only on the virtual appliance platforms. As with RSA certificates, ECC certificates are associated with a network port. You can create multiple virtual ports on the server with each port supporting a specific certificate. For example, external virtual port 1 can use a 1024-bit RSA while external virtual port 2 uses ECC P-256 and external virtual port 3 uses ECC P-384. Only clients that support ECC cipher suites can connect to the web server on that network port.

When an Elliptic Curve Cryptography (ECC) certificate is associated with a network port, only clients that support ECC cipher suites can connect to the Web server on that network port.

Except for the key and certificate generation process, the use of ECC certificates is basically the same as using RSA certificates.

File Management

Overview

The system supports multiple administrator capabilities related to configuration and log file management.

The below list describes the purpose of the different features:

- Archiving- This feature helps to archive system and user configuration files and user logs on a remote backup server. It also helps in scheduling the archiving jobs. The system allows to import the configurations archived.
- Local backup and restore- This feature helps to create backups on the local system and then recover or restore the data during a disaster or while doing significant configuration changes.
- Binary configuration file import/export- This feature helps to export or import the system (system.cfg) and user configuration (user.cfg) in a binary format to replicate the configuration across multiple systems and across the system upgrades.
- XML configuration file import/export- This feature helps to selectively or fully import or export the configuration in an XML format from one IPS device to another. The XML configurations can be modified for system details such as IP address and so on before importing.
- Push Configuration- This feature helps to push a partial configuration from one IPS device to one or more IPS devices directly.

Configuration

The Admin can perform the following configuration procedures:

Archiving

The Admin must configure the archiving backup server details to transfer the files. You can also schedule the archiving jobs.

- The system does not continue to retry the process if it fails, and log files are not deleted.
- It is recommended to schedule an archive operation when traffic is low to minimize its impact on users. The automatic archiving process compresses files and may lead to performance issues.
- The daylight savings time (DST) must be considered while scheduling the archiving.

To configure log archiving:

1. Select **Maintenance > Archiving > Archiving Servers** to display the configuration page.
2. Complete the configuration as described in table.
3. Save the configuration.

Archiving > Archiving Servers

Archiving Servers

Archiving Servers

You can schedule automatic archiving of log data, system configuration, and user accounts. To do so, specify accessible location for the data, an account to use, and the specific schedule for each type of archive data.

▼ Archive Settings

Method: ☒ SCP ☐ FTP ☐ AWS S3 ☐ Azure Storage

☐ Archive XML configuration

☐ Archive Debug Log

☐ Archive Periodic SnapShots

Save Changes

Settings	Guidelines
Archive Settings	
Archive Server	Specify the fully qualified domain name or IPv4/IPv6 address of the server to which to send the archive files.
Destination Directory	Specify the destination directory. Follow these recommendations: For UNIX systems, you can specify an absolute or relative path. We recommend you specify a full path. For Windows systems, specify a path that is relative to the ftp root directory. We recommend you specify a full path.
	Do not include a drive specification for the destination directory, such as: secure/log.
Username	Specify a username that has privileges to log into the server and write to the destination directory.
Password	Specify the corresponding password.
Method	Select SCP, FTP, AWS S3 or Azure Storage. SCP is the default method. SCP is a file transfer utility similar to FTP. SCP encrypts all data during transfer. When the data reaches its destination, it is rendered in its original format. SCP is included in most SSH distributions and is available on all major operating system platforms. AWS S3: Push backup configurations and archived logs to Amazon AWS S3 bucket. For more details, refer to <i>Ivanti Connect Secure Virtual Appliance on Amazon AWS Cloud Deployment Guide</i> . Azure Storage: Push backup configurations and archived logs to Microsoft Azure storage. For more details, refer to <i>Ivanti Connect Secure Virtual Appliance on Microsoft Azure Cloud Deployment Guide</i> .
Archive Schedule	

Settings	Guidelines
Archive events log	<p>Schedule archiving for the Events log. The archive file has the following format: PulseSecureEventsLog-[clustername standalone]-[nodename hostname]-[date]-[time]</p> <p>For example, an archive file for a cluster named Gen has a filename similar to the following: PulseSecureEventsLog-Gen-node1-Root-20090109-1545.gz.</p> <p>The archiving schedule configuration includes the following options:</p> <ul style="list-style-type: none"> • Use this filter-Select a log format filter. • Day of week-Select the days of the week on which to run the archiving job. • Every hour or a Specified Time. Every hour option runs a job every hour on the hour for the selected days. The specified time option runs a job once on the selected days. • Clear log after archiving. Select this option to clear the local log file after the archiving job is successfully completed. If an archive job fails, the log files are not deleted.
Archive user access log	<p>Schedule archiving for the User Access log. The archive file has the following format: PulseSecureAccessLog-[clustername standalone]- [nodename hostname]-[date]-[time]</p> <p>The archiving schedule configuration includes the same options as those described for the Events log.</p>
Archive admin access log	<p>Schedule archiving for the Admin Access log. The archive file has the following format: PulseSecureAdminLog-[clustername standalone]- [nodename hostname]-[date]-[time]</p> <p>The archiving schedule configuration includes the same options as those described for the Events log.</p>
Archive system configuration	<p>Schedule archiving for the system configuration binary file (system.cfg). The archive file has the following format: PulseSecureConf-[clustername standalone]- [nodename hostname]-[date]-[time]</p>

Settings	Guidelines
	The archiving schedule configuration includes the same day, time, and password-protection options as those described for the Events log.
Archive user accounts	<p>Schedule archiving for user account configuration binary file (user.cfg). The archive file has the following format:</p> <p>PulseSecureUserAccounts-[clustername standalone]-[nodename hostname]-[date]-[time]</p> <p>The archiving schedule configuration includes the same day, time, and password-protection options as those described for the Events log.</p>
Archive XML configuration	<p>Schedule archiving for the XML configuration files.</p> <p>The archiving schedule configuration includes the same day and time options as those described for the Events log.</p>
Archive debug log	<p>Enable archiving for collected debug logs.</p> <p>You cannot specify a day and time for archiving debug logs. If you select this option, debug logs are archived periodically and cleared if the Clear log after archiving option is selected.</p>
Archive periodic snapshots	<p>Enable archiving for snapshots.</p> <p>You cannot specify a day and time for archiving periodic snapshots. If you select this option, snapshots are archived periodically.</p>

Backup and Restore

Using the backup and restore feature the Administrator can take the system and user account backup and restore it as needed.

System allows you to save five system configuration backups and five user account backups on the local server.

To manage configuration file backups:

1. Select **Maintenance > Archiving > Local Backups** to display the configuration page.
2. Use the controls to backup or restore the configuration as described in the following table.
3. Save the configuration.

Archiving > Local Backups

Local Backups

Archiving Servers Local Backups

Use Backups to save and restore up to 5 copies of your current system settings or user accounts.

[Save Configuration](#) [Delete](#)

Save Configuration	Create a backup of the running configuration.
Delete	Select a row in the table and click Delete to delete the backup.
Restore	Select a row in the table and click Restore to replace the running configuration with the archived configuration.

Importing/Exporting Binary System Configuration Files

Ivanti Policy Secure(IPS) enables you to import and export the system and network settings using binary system configuration files. When importing a system configuration file, you can exclude the device certificate and the server's IP address or network settings from the imported information. For example, to set up multiple IPS systems behind a load balancer, import everything except for the IP address. To set up the system as a backup server, import everything except for the digital certificate and the network settings. The binary system configuration file includes the following settings:

- **Network settings**
 - **Certificates.** The system imports only device certificates, not the chains that correspond to the device certificates or trusted client CAs.
- **Cluster configuration**
 - **Licenses.** When you import a configuration file that contains licenses, the system gives precedence to any existing licenses. Licenses are imported only if no licenses are currently installed.
- **Client-side logs.** To import or export client-side logs, import or export both the system and user configuration files.

Import of system and user configuration across different hardware platforms is not supported. You can import a FIPS configuration file into a non-FIPS device and vice versa if you do not include the certificate and security world in the import process.

To export a binary system configuration file:

1. Select **Maintenance > Import/Export > Import/Export Configuration** to display the configuration page.

2. Complete the configuration and import/export operation as described in the following table.

Import/Export > System Configuration

System Configuration

Configuration | User Accounts | XML Import/Export

Export

To export system settings to a configuration file, click Save Config As. You can optionally password-protect this file:

Password for configuration file:

Confirm Password:

[Save Config As...](#)

Import

To import system settings from a configuration file, select the configuration file and which settings to bring in, and click Import Config.

Options: ☐ Import Device Certificate(s)?

Note: Checking this will overwrite the existing Device Certificate(s).

Other Import Options:

- ☐ Import everything (except Device Certificate(s))
- ☐ Import everything but the IP address

Preserves the IP address, netmask, default gateway, VIPs, ARPs and routes of the network interfaces on this device.

Note: Use this option only if the exported configuration file is from a standalone node.
- ☒ Import everything except network settings, cluster settings and licenses

Leaves everything in Network Settings, Clustering Properties, Licensing sections and Onboarding Profile UUID unchanged.

Note: Always use this option if configuration file was exported from a node that is part of a cluster.
- ☐ Import only Device Certificate(s)

Imports the Device Certificate(s) only.

Note: You must check the Import Device Certificate(s) checkbox above.

Config File: [Browse](#) No file chosen

Password: Use this if the configuration file was password-protected

Note that importing configuration with a different SSL acceleration setting will reboot the IVE.

Import Config	Import the configuration file.

Importing/Exporting Binary User Configuration Files

Ivanti Policy Secure(IPS) allows you to import/export the system and network settings using binary configuration files. In general, if a menu item falls under the Authentication, Administration, or Users menu, the item is included in the user configuration file (user.cfg).

The user configuration file includes the following settings:

- Sign-in settings (includes sign-in policies, sign-in pages, all authentication servers, authentication protocol sets, Ivanti Secure Access Client settings)
- Authentication realms (including admin realms, user realms, and MAC authentication realms)
- Roles
- Network access.
- Infranet Enforcers.
- Host Enforcer.
- Resource policies
- User accounts
- Client-side logs. To export or import client-side logs, export or import both the system and user configuration files.

To export a binary user configuration file:

1. Select **Maintenance > Import/Export > Import/Export Users** to display the configuration page.

2. Complete the configuration and export/import operation as described in the following table.

The screenshot shows the 'User Configuration' interface with three tabs: 'Configuration', 'User Accounts' (selected), and 'XML Import/Export'. The 'Export' section is expanded, showing instructions to export user settings to a configuration file, with optional password protection. It includes input fields for 'Password for configuration file' and 'Confirm Password', a 'Save Config As...' button, and an 'Import' section with a 'Browse' button, a password field, and an 'Import Config' button.

Settings	Guidelines
Password	Specify the password (if applicable).
Import Config	Import the configuration file.

Importing/Exporting XML Configuration Files

The Admin can save the system and user configuration in XML format. This enables the system to replicate the configurations.

This will help in the following use cases:

- Adding to the configurations of peer nodes, for example, adding many users.
- Modifying multiple instances of a single setting, for example, an authentication server name.
- Deleting settings, for example, deleting authentication servers that are no longer used.
- Creating a configuration template to use for setting up new nodes.
- Tracking configuration changes by comparing differences on periodic exports.

Guidelines and Limitations

Table summarizes the guidelines and limitations for using the XML import/export feature.

Category	Guidelines and Limitations
General	<p>The following guidelines and limitations apply:</p> <ul style="list-style-type: none">• You can import and export configuration files only between systems running the same software version.• You might find it useful to use a text editor to modify configuration elements that ought to be distinguished, such as configuration object names and descriptions. Never modify the names of the NIC identifiers. The system relies on knowing that each appliance has two interface cards, known as NIC0 and NIC1.

Category	Guidelines and Limitations
	<ul style="list-style-type: none">Immediately after importing an Active Directory authentication server configuration, you must edit the configuration to change the Computer Object name. Unexpected problems might arise if two systems join an Active Directory domain using the same Computer Object name.
Licenses	<p>The following rules apply to exported and imported licenses:</p> <ul style="list-style-type: none">You cannot edit the license data that is exported. It is encrypted.An XML import of licenses is valid only if the system does not currently have a license installed. If a license is installed already, any imported licenses are dropped. If you still intend to import a license, you must perform a factory reset before you perform the import operation.If you import a license after deleting a temporary license, the imported license is dropped because you might still be able to reactivate the deleted license. The import operation preserves any licensing data.
Clusters	<p>The following guidelines apply to importing a configuration file for nodes that belong to a cluster:</p> <ul style="list-style-type: none">When you perform an import operation on a cluster, all the cluster nodes must be enabled and running. If you attempt to import a configuration into a cluster in which a node is not running, the import operation might hang or your import results might be unpredictable.The XML configuration that you import must contain the same set of nodes as the original cluster. The signature used to synchronize the cluster when the nodes are reenabled is derived from the IP addresses of the cluster nodes. Therefore, the remaining nodes cannot rejoin the cluster if the imported configuration yields a different signature.When import occurs, the imported configuration file overwrites the node-specific cluster configuration network settings of the remaining nodes. If you change the node-specific network settings, make sure you do not make the remaining nodes unreachable.After you have exported the file, do not modify settings that could render the primary node unreachable, such as changes to network settings.

Category	Guidelines and Limitations
	<ul style="list-style-type: none">• After you have exported the file, do not modify the XML to change the node name, IP address, or IP netmask.• After you have exported the file, do not modify virtual port settings or add new virtual port settings.

To export/import an XML configuration file:

1. Select **Maintenance > Import/Export > Export/Import XML** to display the configuration page.

2. Complete the configuration and export/import operation as described in the following table.

Import/Export > Export XML

Export

Modifying Configuration XML Files

This topic provides guidelines for modifying an exported configuration file.

Understanding the XML Export File

When you export a configuration file, the system saves the configuration as an XML file. The data in the exported file is based on the selections you make when you configure the export operation. The file contains all the required XML processing instructions and namespace declarations, which must be included exactly as defined.

Table provides some basic information and guidelines to help you understand the structured XML used in the export file.

Topic	Guideline
XML schema definition (.xsd) file	<p>The export is based on an XML schema. The schema is a separate file that defines the metadata, and that serves as a model or a template for the exported file. Use the XML schema file to:</p> <ul style="list-style-type: none">• Identify the structure and sequence of configuration objects.• Identify optional and required elements, allowable values, default values, and other attributes of the configuration objects. <p>You can download the XML schema definition (.xsd) file in either of the following ways:</p> <ul style="list-style-type: none">• From the XML Import/Export pages by clicking a link.• From the URL where the files are stored on the system (you do not need to sign in). <p>To access the .xsd file, access the following URL: <code>https://<IP-or-hostname>/dana-na/xml/config.xsd</code></p>
Elements	<p>An element is a discrete XML unit that defines an object or part of an object. The element typically consists of a pair of tags that may or may not surround string data. Tags are surrounded by angle brackets (< >).</p>

Topic	Guideline
Namespaces	<p>Namespaces allow you to use the same words or labels in your code from different contexts or XML vocabularies. Prefixing elements with namespace qualifiers allows the XML file to include references to different objects that originate in different XML vocabularies and that share the same name. If you do not prefix elements with namespace qualifiers, the namespace is the default XML namespace, and you refer to element type names in that namespace without a prefix.</p> <p>When you see namespace identifiers in your XML files, you do not need to be concerned about them, as long as you do not delete or modify the identifiers.</p>
Element Sequence	<p>You should avoid changing the sequence of elements in the XML file, whenever possible. Although the schema does not enforce sequence in all cases, you gain no benefit from changing the order of elements from the order in which they appear in the exported file, and, in some cases, you might invalidate the XML structure by changing element sequence.</p>

Every XML tag fits into one of the following XML tag types:

- Start tag—Defines the beginning of an element. The start tag consists of an open angle bracket (<), a name, zero or more attributes, and a close angle bracket (>). Every start tag must be followed by an end tag at some point in the document.
- End tag—Defines the end of an element. The end tag consists of an open angle bracket and a forward slash (</), followed by the same name defined in its corresponding start tag, and ends with a close angle bracket (>).
- Empty tag—The empty tag is denoted in two forms. If a tag pair has no data between them, the tag pair is considered an empty tag. Officially, according to the XML specification, an empty tag looks something like this:
<<empty tag example/>>

In this form, the empty tag consists of an open angle bracket (<), followed by an element name, a slash and a close angle bracket (>). When you see an empty tag in your configuration files, it signifies an element that the schema requires to be included in the XML file, but whose data is optional.

Start tags can contain attributes, and tag pairs (elements) can contain additional elements. The following example shows an XML file for the Users object. In this example, you see only the Administrator configuration settings.

```
<configuration xmlns="http://xml.sample.net/x"
```

```
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <authentication>
    <auth-servers>
      <auth-server>
        <local>
          <users>
            <user>
              <username>admin</username>
              <fullname>Platform Administrator</fullname>
              <password-encrypted>3u+U</password-encrypted>
              <one-time-use>false</one-time-use>
              <enabled>true</enabled>
              <change-password-at-signin>false</change-password-at-signin>
            </user>
          </users>
        </local>
        <name>Administrators</name>
      </auth-server>
```

You make changes to the string data that is displayed between start and end tags. For example, using the preceding example, you can add to or change the following elements:

- <username>admin</username>
- <fullname>Platform Administrator</fullname>
- <password-cleartext>password</password-cleartext>
- <change-password-at-signin>false</change-password-at-signin>
- <name>Administrators</name>

The preceding sample displays the password element's data as encrypted data. You can modify the password if you change the element to password-clear text. If you modify the password, the password value is visible until it is imported back into the system. Once imported, the system encrypts the password.

If you enter passwords for new users in clear text format, the passwords are visible in the file, therefore, you might consider setting the Change Password at Next Login option to true.

- Use the password-clear text element and enter a text password when changing passwords through the XML file.
 - If you change a user for a given authentication server or an authentication server for a given user, you are creating a different user, not updating an existing user or authentication server. User and authentication server together logically define a unique user.
-

Comparing Configuration Settings

The elements in the XML file are closely related to the objects and their options as you see them in the admin console. The element names in the XML instance file correlate closely with the displayed object and option names.

For example, select **Users > User Roles > [Role] > General > Session Options**. The admin console renders the possible values for a roaming session as an option button group, consisting of the values:

- Enabled
- Limit to subnet
- Disabled

The following snippet from the exported configuration file shows the session options for the Users role. On the bolded line, the roaming session option is disabled:

```
<session-options><SessionOptions>  
  <MaxTimeout>60</MaxTimeout>  
  <RoamingNetmask />  
  <Roaming>disabled</Roaming>  
  <PersistentSession>>false</PersistentSession>  
</SessionOptions>
```

In the schema file, you can locate the allowable values for the roaming session option:

```

<Attribute roaming:START>
<xsd:element name="roaming" minOccurs="0">
...
  <xsd:enumeration value="enabled">
...
  <xsd:enumeration value="limit-to-subnet">
...
  <xsd:enumeration value="disabled">
...
</xsd:element>
<Attribute roaming:END>

```

To change the value for the roaming session from Disabled to Limit to subnet, replace disabled with limit-to-subnet.

This example shows that the admin console often provides all the allowable values, displayed either in an option button group, as check boxes, as list boxes, or as other types of user interface components. The XML file displays only the current state of your configuration. The schema file displays all the actual values for the configuration options that are supported.

Understanding Referential Integrity Constraints

The system configuration objects are part of a data model that is enforced using referential integrity constraints. You cannot change these constraints, but you should understand them before you attempt to delete objects that maintain dependencies to other objects.

If you violate the referential integrity constraints, your import operation fails.

In the figure, the boxes represent object types and the arrows represent dependent relationships between the object types. Arrows point from dependent objects to objects.

The system does not allow you to delete an object on which another object depends. Conversely, when you add an object, you must add any other objects on which that object depends.

Sign-in URLs depend upon realms and sign-in pages. Realms depend upon both authentication servers and roles. Policies depend upon roles. Users depend upon authentication servers.

Consider the following scenarios based on the preceding figure:

If you add sign-in URLs, you must add realms, sign-in pages, roles, and authentication servers. You need to add an authentication server and at least one role to support the realm, and you must add the realm and the sign-in page to support the new sign-in URL.

- If you add a user, you must be able to assign it to an authentication server. If there is no authentication server on the target node yet, you must add one in the XML file.
- If you add a policy, you must be able to assign it to a role. If there is no role on the target system, you must add one in the XML file.
- If you delete an authentication server, you might strand realms and users, therefore, you need to make sure no realms or users depend on the authentication server before you attempt to delete it.
- If you delete a role, you might strand policies and realms. To delete a role, you must first delete any policy that depends upon the role, or reassign associated policies to another role. Also, to delete a role, you must first delete or reassign any realm that depends upon that role.
- If you delete a sign-in page, you might strand one or more sign-in URLs. To delete a sign-in page, you must first delete any associated sign-in URLs or reassign them to other sign-in pages.

Referential integrity checks are performed only during XML import.

Using Operation Attributes

Operation attributes define the positioning or action of XML data within the schema. If you do not specify an operation attribute, the modified data is merged by default.

XML data with an operation attribute has the following format:

```
<object1 xc:operation="operator for object1 and its children unless new operator is defined">
....
<object2>
...
<object3 xc:operation="operator for object3">
...
</object3>
...
</object2>
...
</object1>
```

The operation attribute is applied to all children objects unless a different operation attribute is defined in children objects.

The following operation attributes are supported:

- **Merge**—The configuration data identified by the element that contains this attribute is merged with the configuration at the corresponding level in the configuration datastore identified by the target parameter. This is the default behavior.
- **Replace**—The configuration data identified by the element that contains this attribute replaces any related configuration in the configuration datastore identified by the target parameter. Only the configuration present in the configuration parameter is affected.
- **Create**—The configuration data identified by the element that contains this attribute is added to the configuration if and only if the configuration data does not already exist on the device.
- **Delete**—The configuration data identified by the element that contains this attribute is deleted in the configuration datastore identified by the target parameter.
- **Insert before**—Changes the position of a configuration element in an ordered set.
- **Insert after**—Changes the position of a configuration element in an ordered set.
- **Rename**—Changes the name of one or more of a configuration object's identifiers.

If you are merging a list of objects to an existing list of objects in the configuration store, the results of the merged list might be unexpected. During a merge operation, the order of the objects in the new list is not maintained. If you are importing a list of objects and would like to preserve the order of the new list, you should use the replace operation attribute. You can also use insert before or insert after to ensure that you produce the hierarchy that you intended.

Operation attributes are applied to elements recursively unless new operators are also defined within lower-level elements. There are limitations on the legal operator that can be used in child elements without conflict with the parent operator. Table shows the legal operator relationships between parent and child elements.

Child > V-Parent	Create	Merge	Replace	Delete	Insert before	Insert after	Rename
None	OK	OK	OK	OK	OK	OK	OK
Create	OK	OK	Error	Error	OK	OK	Error
Merge	OK	OK	OK	OK	OK	OK	OK
Replace	Error	OK	OK	Error	OK	OK	Error
Delete	Error	OK	Error	OK	Error	Error	Error
Insert Before	OK	OK	OK	OK	OK	OK	OK
Insert After	OK	OK	OK	OK	OK	OK	OK
Rename	OK	OK	OK	OK	OK	OK	OK

The following examples demonstrate the import operation:

Example 1: Set the MTU to 1500 on an interface named "Ethernet0/0" in the running configuration.

```
<interface>
  <name>Ethernet0/0</name>
  <mtu>1500</mtu>
</interface>
```

Example 2: Add an interface named "Ethernet0/0" to the running configuration, replacing any previous interface with that name.

```
<interface xc:operation="replace">
  <name>Ethernet0/0</name>
  <mtu>1500</mtu>
  <address>
    <name>192.0.2.4</name>
    <prefix-length>24</prefix-length>
  </address>
</interface>
```

The default import modes have the following equivalent attributes on the root object of the configuration tree:

- Standard Import is always a merge operation.
 - Quick Import is a create operation.
 - Full Import is a replace operation.
-

Example: Importing/Exporting XML file configuration to add Multiple Users

This example shows how to use the configuration XML file import/export feature. The example is illustrative. There are additional ways to use export files.

Assume you have just added a new device to the network, and you want to add your 2,000 users to the system. Instead of adding them one at a time in the admin console, you want to perform a mass import. You can export the user accounts, extract the relevant XML that defines users, replicate each element as needed, and then import them. In this situation, your configuration should include the option to force the users to change their passwords the first time they log in to the system.

In this procedure, you only see examples for User 1, User 2, and User 2000. All other users are included in your import file. You set the passwords to numbered instances of the word password, such as password1, password2, and so on. All users in this example are assigned to the same auth server, although you can specify any combination of auth servers that are valid on your system.

To add multiple new users:

1. Select **Maintenance > Import/Export > Export XML**.
2. Follow the instructions to export local user accounts.
3. Save the exported file as users.xml.
4. Open the users.xml file.
5. Copy and paste the User container element repeatedly until you have added the necessary number of users. Although the example shows only three new users, you might add hundreds of new users to the file.
6. Update the appropriate data in each User container element as shown in [Example: Updating the User container](#).
7. Save the users.xml file.

8. Select **Maintenance > Import/Export > XML Import/Export > Import**.
9. Click **Browse** to locate and select your users.xml file.
10. Click **Import**.

Example: Updating the User container

```
<configuration xmlns="http://xml.sample.net/x/x"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <authentication>
    <auth-servers>
      <auth-server>
        <local>
          <users>
            <user>
              <username>user1</username>
              <fullname>User1</fullname>
              <password-cleartext>password1

              </password-cleartext>
              <one-time-use>false</one-time-use>
              <enabled>true</enabled>
              <change-password-at-signin>true

            </change-password-at-signin>
          </user>
          <user>
            <username>user2</username>
            <fullname>User2</fullname>
            <password-cleartext>password2

            </password-cleartext>
            <one-time-use>false</one-time-use>
            <enabled>true</enabled>
            <change-password-at-signin>true
```

```
</change-password-at-signin>
</user>
<name>System Local</name>
</auth-server>
</auth-servers>
</authentication>
</configuration>
```

Pushing the Configuration

The push configuration feature supports simple configuration management across an enterprise without requiring you to deploy the systems as a cluster. You push a partial configuration from the running configuration on the source system to the running configuration on one or more target systems.

It is not desirable to push some groups of settings to a running configuration, so the following groups of settings are not supported:

- Network configurations
- Licenses
- Cluster configurations
- Certificates
- SNMP settings
- Syslog server settings
- Push configuration targets

Guidelines and Limitations

Table summarizes the guidelines and limitations for using the push configuration feature.

Category	Guidelines and Limitations
General	The following guidelines and limitations apply:

Category	Guidelines and Limitations
	<ul style="list-style-type: none">• You can push a configuration to systems running the same software version (same build number) or higher software version.• The source device pushes data over the management port (if configured) or the internal port. The target device can receive data over the internal or external port or management port.• You can push to a single target or to multiple targets. For example, if you install several new systems, you can push a common configuration to set their initial configuration.• When a configuration push job begins on a target, no warning is displayed, and the administrators are automatically logged out to avoid potential conflicts.• For selected configuration push, if the configuration to be pushed contains one or more JAM packages, we recommend you to push the JAM packages first considering one JAM package per push and then push the remaining configurations.• When the job has completed on a target, the target device restarts its services. Brief interrupts might occur while the service restarts. You must push to targets when they are idle or when you can accommodate brief interruptions.• You must delete the failed push jobs before performing a new push.• For entire configuration push, when pushing settings such as FIPS settings, security settings on a target even though the job has completed on a target, you might see a connection lost message on the source. You can resume the actual job to see the status and even though the source says connection lost the import will be successful.
Licenses	The push configuration job does not push licenses or licensing settings.
Clusters	<ul style="list-style-type: none">• You can push a configuration to target that is a member of a cluster, if the target is not a member of the same cluster as the source.

Category	Guidelines and Limitations
	<ul style="list-style-type: none">• You can push a configuration to multiple targets, if targets are not part of the same cluster.• You must not perform the clustering operations such as adding a cluster, deleting a cluster, and so on when performing a push configuration. If such events occur, then unsuccessful jobs will be aborted and the backup files will be deleted.• You must not use VIPs during push configuration. Instead you must use the internal IP or the management IP of one of the nodes to create the target.• You must delete the backed-up configuration on the target node(s) as soon as possible to free up the disk space.

Configuring Targets

To configure push configuration targets:

1. Select **Maintenance > Push Config > Targets** to display the target list and source options configuration page.
2. Complete the configuration for the source options as described in table.
3. Click **New Target** to display the configuration page for targets.
4. Complete the configuration as described in table.

5. Save the configuration.

Push Configuration > Targets

Targets

Push Configuration **Targets** Results History

☒ Allow this Pulse Policy Secure to be a target
This Pulse Policy Secure will accept configuration pushed from another Pulse Policy Secure. This box must be checked on each target that is configured on this page.

☐ Validate target server certificate
To be configured on source device. This enables source device to validate target device server certificate before pushing configuration.

[New Target...](#) [Delete...](#) [Save Changes](#)

10 records per page Search:

<input type="checkbox"/>	Target Name	Target Sign-in URL	Admin Username	Auth. Realm
<input type="checkbox"/>				

Settings	Guidelines
Allow this system to be a target	Select this option to allow the system to accept configuration pushed from another system. This option must be selected on targets, but does not have to be selected on the source system.
Validate target server certificate	Select this option on the source system if you want the source system to validate the target system server certificate before pushing the configuration.
Save Changes	Click this button if you have changed the source device configuration options described above.
Delete	Select a row in the table and click Delete to remove the target from the list. You cannot delete a target if it has push configuration results associated with that target.

Push Configuration > Targets > New Target

New Target

Name: *

Sign-in URL: *

Admin Username: *

Password: *

Auth. Realm: *

[Save Changes](#)

*indicates required field

Settings	Guidelines
Name	Specify a name to identify the target within the system. Target names and target sign-in URLs cannot be edited after they have been saved.
Sign-in URL	Specify the URL for the administrator sign-in page. Sign-in URLs cannot be edited after they have been saved.
Admin Username	Specify an account on the target system that the push configuration job can use to sign-in and make changes to the configuration. The job can make wide-ranging configuration changes, so the user must have full administrative privileges. In other words, the user must belong to the Administrators role.
Password	Specify the corresponding password.
Auth. Realm	Specify the administrator authentication realm on the target system. The access management framework must be configured so that the job process (run as the username specified above) can sign in without any human interaction. For example, you cannot have dynamic credentials or multiple roles that are not merged, as these both require manual interaction.

Settings	Guidelines
	We recommend that you create an administrator account on each target that can be used exclusively for push configuration. Configure the administrator realm so that the realm policy and role mapping rules do not result in prompts requiring human interaction. For example, the user must be able to log in with static password authentication or two-factor tokens that do not use challenge-response type authentication. For example, certificates, Soft ID, and Defender Authentication are not supported.

Configuring Push Settings

To configure the settings to be pushed:

1. Select **Maintenance > Push Config > Push Configuration** to display the configuration page.

2. Complete the configuration and push configuration operation as described in the following table.

Select Settings and Export	
What to push	<p>Select Selected configuration or Entire configuration.</p> <p>If you select Selected configuration, the page displays controls to select settings groups.</p> <p>If you select Entire configuration, all settings from the source system are pushed, except for the following:</p> <ul style="list-style-type: none">Network configurations

Settings	Guidelines
	<ul style="list-style-type: none"> • Licenses • Cluster configurations • Certificates • SNMP settings • Syslog server settings • Push configuration targets
Expand All	Click this button to expand the display of all settings groups.
Select All	Click this button to select all settings for all groups.
Settings	
System	Expand this group and select settings found under the System menu. NOTE: You cannot push host-specific network settings to a target. If you want to copy these settings to another system, use the configuration XML file import/export feature.
Sign-in	Expand this group and select settings found under the Sign-in menu.
Endpoint Security	Expand this group and select settings found under the Endpoint Security menu. <div>  ESAP packages are encrypted when exported. </div>
Authentication Realms	Expand this group and select authentication realm settings, including user realms and MAC address authentication realms.
Roles	Expand this group and select settings found under the Roles menu.
Resource Policies	Expand this group and select settings resource policies settings.
Ivanti Secure Access Client	Expand this group and select settings found under the menu.

Settings	Guidelines
Local User Accounts	Expand this group and select local authentication server settings.
Infranet Enforcer	Policy Secure only. Expand this group and select settings found under the Infranet Enforcer menu.
Network Access	Policy Secure only. Expand this group and select settings found under the Network Access menu.
Maintenance	Expand this group and select settings found under the Maintenance menu.
Push Configuration	
Available Targets / Selected Targets	Use the Add and Remove buttons to select the targets.
Overwrite duplicate settings	Select this option to overwrite settings on the target that have the same name as settings being pushed. If you do not select this option, the push configuration job copies only configuration objects that have names different from the configuration objects on the target.
Allow Rollback to previous configuration	Select this option to revert to a previous configuration state, effectively rolling back configuration changes. If you select this option, the local configurations on the target node will be backed up before importing the configurations. You can also undo the push configuration if you want to discard the changes and revert to the previous state. We recommend you to delete the backed-up configuration if the import is successful. <div>  If the target configuration is large the rollback of configurations can take several minutes to complete. </div>
Description	Enter the description for the job. The job description is limited to 100 characters.

Settings	Guidelines
Schedule Import on Target	Select this option to allow a delayed import on the target node. If you select this option, the selection applies to all the targets in the job. The import schedule is measured in HH:MM (hours, minutes) format. The schedule is specified according to source's time zone.
Push Configuration	<p>Click this button to push the selected configuration data to the specified targets.</p> <p>You can pause the push for a target during the push process. If errors occur during the push process, the job stops, and the configuration for the target is not imported. However, you can resume the failed push jobs. Error messages are displayed on the Results page.</p> <p>If you have specified multiple targets and a push configuration job to a target fails, the job continues to the next target until specified targets are updated (or fail). The results page displays the status and any problems encountered during the process.</p>

Viewing Configuration Push Results

Purpose	The source system saves and displays the push configuration results in the Results tab.
Action	To view push configuration job results:

1. Click the Select **Maintenance > Push Config > Results** to display the results page.
2. Click a job name to display additional information about the job.

3. Select a job and click **Delete** to remove it from the results page.

The following table describes the information displayed on the Results page and the various management tasks you can perform.

GUI Element	Guidelines
Disk Usage Details	<p>Displays the disk space available for push configuration and the disk space consumed by all the push jobs in the device.</p> <p>The disk space consumed by individual push jobs are also mentioned across each push job under the disk usage column. When total disk space consumed reaches the total disk space push jobs may fail and you can see the results column to see the failure message. You need to monitor the disk space consumed by push configuration to avoid push failures related to disk space limits.</p>

GUI Element	Guidelines
Description Column	Displays the type of the push configuration.
Disk Usage Column	Displays the disk space used by the job.
Results Column	Displays the status of the transfer and result of post push action. It also displays the status of the push such as log in, export, transfer, backup, import and so on. The status result message shows the type of data that is getting transferred. For a paused or failed target the information on the current state of the job when it is paused, or failure reasons if any is displayed. This column also shows the progress of data transfer using a bar chart. For selected push, additional configuration data (additional configuration data refers to configuration that is transferred only if it is modified or not available on the target) includes ESAP package, JAM package, VDI configurations, Terminal services, Host Checker files, Custom sign in pages and notifications, and Applet files. For complete configuration push, additional data includes ESAP and JAM packages.
Post Push Action	Displays the options that the user can perform after the push such as roll back and delete backup. It also displays the post push actions such as rollback done, backup deleted, rollback failed, performing rollback, deleting back up and so on.
Resume	Select this option to resume a paused or a failed push.
Undo	Select this option to rollback to previous configuration that was backed up. Note that you can perform this operation only when the push is successful and Allow Rollback to Previous Configuration is selected. This option is available only if the backup is not deleted or undo is not done yet.
Abort	Select this option to cancel an entire push job or push to target within a job. An aborted push cannot be resumed.
Pause	Select this option to temporarily pause the push operation to a specified target.
Delete Backup	Select this option to delete the backup configuration on the specified target. Note that this option is available only when the users selects the Allow Rollback to Previous Configuration option during the push job.

Viewing Configuration Push History

Purpose	The source/target system saves and displays up to 5 push history results per target/source in the History tab. When the history table reaches 5 entries, the system removes the oldest result data when the next push configuration job is started.
Action	To view push configuration push history:

1. Select **Maintenance > Push Config > History** to display the history page.
2. Examine the history to verify success or learn the reasons the push job failed. The history page displays rollback history however the failure reason is not displayed. You can check the failure reason in the details page for each job. It also displays the timestamp history information of successful, failed push jobs, or if a configuration is undone.
3. Select the source name and click **Delete** History to remove it from the History page.

FIPS Level 1 Support

FIPS Level 1 Support Software FIPS

Federal Information Processing Standard (FIPS) are a set of standards that define security requirements for products that implement cryptographic modules used to secure sensitive but unclassified information. The most recent standards are defined in the FIPS Publication 140-2.

The FIPS documents define, among other things, security levels for computer and networking equipment. U.S. Federal Government departments, and other organizations, use FIPS to evaluate the cryptographic capabilities of the equipment they consider for purchase. Cryptographic modules are validated against separate areas of the FIPS specification. An overall certification level is assigned based on the minimum level achieved in any area. Although primarily aimed at environments requiring strict security, FIPS levels are increasingly enforced as qualifying criteria for all U.S. Federal Government contracts. Security-conscious private enterprises might also use FIPS levels as an equipment evaluation benchmark. FIPS levels also serve as a customer-neutral description of vendor requirements. Vendors can engineer security products to FIPS levels and extend the applicability and eligibility of these products across a broad customer base, thereby eliminating exhaustive and time-consuming customer-by-customer product qualification procedures.

Ivanti offers FIPS level 1 support for IPS. Both services use a 140-2 level 1 certified cryptographic module to comply with FIPS. When FIPS level 1 support is enabled applications, such as browsers, accessing the web server must support Transport Layer Security (TLS), the latest version of Secure Socket Layer (SSL). If the platform features hardware acceleration, then for SSL processing SSL hardware acceleration is disabled as hardware acceleration does not comply with FIPS validation. Only FIPS approved algorithms are used when in FIPS level 1 support is enabled.

For more information about the Ivanti Cryptographic Module, see the [security policy](#) and the [validation certificate](#). For a complete list of validated FIPS 140-1 and FIPS 140-2 cryptography modules, see <http://csrc.nist.gov/groups/STM/cmvp/documents/140-1/140val-all.htm#2018>.

FIPS Supported Platforms

The following platforms support FIPS level 1:

- ISA 6000,8000,
- IPS virtual appliances

FIPS Level 1 Support

Problem: If you have FIPS level 1 support enabled and your browser does not support the required cipher suites, you cannot access the device. If this happens to an administrator account, you can no longer administer or configure the system.

Solution: You can turn off FIPS level 1 support and reset the encryption strength from the device's serial console. After choosing that option, SSL options are reset to Accept only TLS 1.0 and later and to **Maximize Compatibility (Medium Ciphers)**.

Open a serial console to your device and select option 8. **Turn off FIPS Mode and reset allowed encryption strength for SSL.**

Turning Off FIPS Level 1 and Resetting Encryption Strength from the Serial Console

Please choose the operation to perform:

1. Network Settings and Tools
 2. Create admin username and password
 3. Display log/status
 4. System Operations
 5. Toggle password protection for the console (Off)
 6. Create a Super Admin session.
 7. System Maintenance
 8. Turn off FIPS Mode and reset allowed encryption strength for SSL
- Choice: 8

Once you turn off FIPS level 1 support, option 8 is relabeled "Reset allowed encryption strength for SSL."

Supported Cipher Suites

When FIPS level 1 support is enabled, only TLSv1.0, v1.1, v1.2 and AES256, 3DES and AES128 are allowed. The order of the cipher suites is not dependent on the SSL hardware acceleration module since hardware acceleration is not used when FIPS level 1 support is enabled.

When FIPS level 1 support is enabled, the following settings are automatically configured:

- In the SSL Options window:
 - Under Allowed SSL and TLS Version, the **Accept only TLS** option is selected. All other options under this section are disabled.
 - Under Allowed Encryption Strength, the **Maximize Compatibility (Medium Ciphers)** option is selected. Only FIPS approved ciphers are selected.
 - Under Encryption Strength Option, the **Do not allow connections from browsers that only accept weaker ciphers** option is selected.
- SSL hardware acceleration is disabled. IPsec hardware acceleration is not affected by the FIPS level 1 support being enabled.

The first four cipher suites in the below table are given preference due to the requirements in RFC 6460. The first two cipher suites meeting the requirement for Suite B Profile for TLS 1.2. The next two meeting the requirement for Suite B Transitional Profile for TLS 1.0 and 1.1.

Cipher Suite	Protocol
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256	TLSv1.2
TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384	TLSv1.2
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384	TLSv1.2
TLS_ECDH_RSA_WITH_AES_256_GCM_SHA384	TLSv1.2
TLS_ECDH_ECDSA_WITH_AES_256_GCM_SHA384	TLSv1.2
TLS_ECDH_RSA_WITH_AES_256_CBC_SHA384	TLSv1.2
TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA384	TLSv1.2
TLS_ECDH_RSA_WITH_AES_256_CBC_SHA	TLSv1.0 and later
TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_ECDSA_WITH_3DES_EDE_CBC_SHA	TLSv1.0 and later

Cipher Suite	Protocol
TLS_ECDH_RSA_WITH_3DES_EDE_CBC_SHA	TLSv1.0 and later
TLS_ECDH_ECDSA_WITH_3DES_EDE_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256	TLSv1.2
TLS_ECDH_RSA_WITH_AES_128_GCM_SHA256	TLSv1.2
TLS_ECDH_ECDSA_WITH_AES_128_GCM_SHA256	TLSv1.2
TLS_ECDH_RSA_WITH_AES_128_CBC_SHA256	TLSv1.2
TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256	TLSv1.2
TLS_DHE_RSA_WITH_AES_256_CBC_SHA	TLSv1.0 and later
TLS_DHE_RSA_WITH_AES_128_CBC_SHA	TLSv1.0 and later

Cipher Suite	Protocol
TLS_RSA_WITH_AES_256_CBC_SHA256	TLSv1.2
TLS_RSA_WITH_AES_256_CBC_SHA	TLSv1.0 and later
TLS_RSA_WITH_3DES_EDE_CBC_SHA	TLSv1.0 and later
TLS_RSA_WITH_AES_128_CBC_SHA256	TLSv1.2
TLS_RSA_WITH_AES_128_CBC_SHA	TLSv1.0 and later
TLS_RSA_WITH_AES_256_GCM_SHA384	TLSv1.2
TLS_RSA_WITH_AES_128_GCM_SHA256	TLSv1.2
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	TLSv1.2
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	TLSv1.2
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	TLSv1.0 and later

Cipher Suite	Protocol
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	TLSv1.2
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	TLSv1.2
TLS_DHE_RSA_WITH_AES_256_CBC_SHA	TLS1.0 and later
TLS_DHE_RSA_WITH_AES_128_CBC_SHA	TLS1.0 and later

Cipher Suite	Protocol
TLS_RSA_WITH_AES_256_CBC_SHA256	TLSv1.2
TLS_RSA_WITH_AES_256_CBC_SHA	TLSv1.0 and later
TLS_RSA_WITH_3DES_EDE_CBC_SHA	TLSv1.0 and later
TLS_RSA_WITH_AES_128_CBC_SHA256	TLSv1.2
TLS_RSA_WITH_AES_128_CBC_SHA	TLSv1.0 and later
TLS_RSA_WITH_AES_256_GCM_SHA384	TLSv1.2
TLS_RSA_WITH_AES_128_GCM_SHA256	TLSv1.2
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	TLSv1.2
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	TLSv1.2
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	TLSv1.0 and later
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	TLSv1.2
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	TLSv1.2
TLS_DHE_RSA_WITH_AES_256_CBC_SHA	TLS1.0 and later
TLS_DHE_RSA_WITH_AES_128_CBC_SHA	TLS1.0 and later

Cipher Suite	Protocol
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256	TLSv1.2
TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384	TLSv1.2

TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256	TLSv1.2
TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA	TLS1.0 and later

Dashboard and Reports

Dashboard and Report Overview

A dashboard is an interface used to manage the access management framework. It provides an integrated view of all devices and users accessing the network, their device profile information, authentication methods used to gain access, device posture compliance and so on.

A report is an element of a dashboard used to convey complex data in simplified formats. Access management framework collects log and configuration data from across your network, and it then aggregates the data into reports for you to view and analyze. It provides a standard set of predefined reports that you can use and customize to fit your needs. The reports are grouped into logical categories for information related to authentication, session traffic, device administration, configuration and administration, and troubleshooting.

You can use the system dashboard and reports to analyze system utilization.

Enabling the Dashboard

You can use the admin console to enable or disable the dashboard.

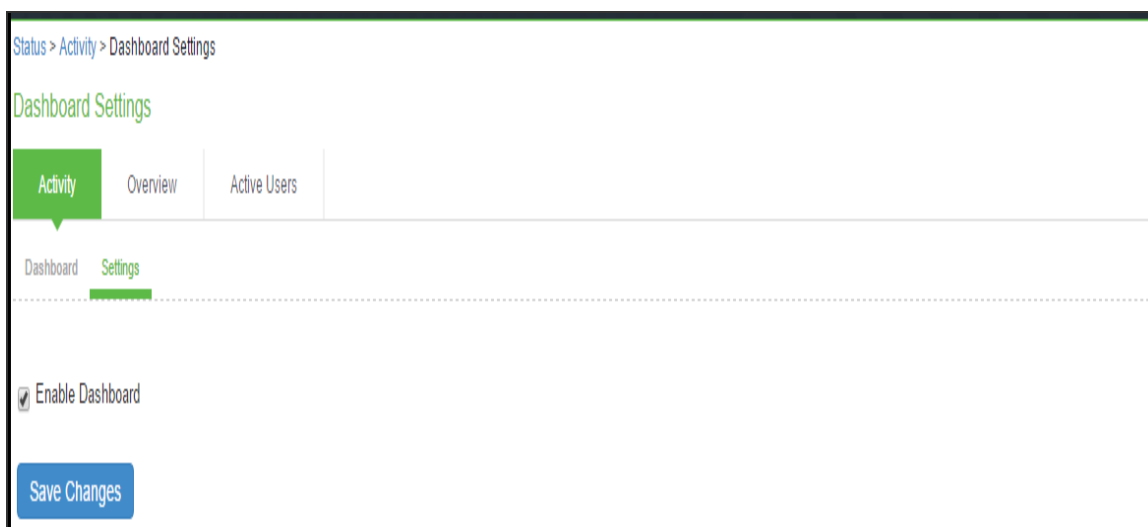

To enable the dashboard.

1. Select **System > Status > Activity > Settings**.
2. Select **Enable Dashboard**.

The dashboard is enabled by default.

The following figure shows the dashboard settings for IPS.

Using the Dashboard

Dashboard Overview

The dashboard contains six default graphic reports focused on security, network activity, application activity, system monitoring, and compliance.

Metric	Description
Policy Secure	
Total Endpoints	The total number of unique endpoints over a time. If an endpoint provides a unique identifier (mobile device ID, client ID, and so on), then it will be used to identify the endpoint. For a browser-based session where an identifier is not available, each session is considered a unique endpoint.
Active Endpoints	The total number of unique endpoints with active sessions.
Active Guests	The total number of active guest users. A guest user is defined as a user with an expiration date. This includes administrator-created and GUAM-created guest users. This does not include GUAM-created users without expiration dates.
Active MAC Auth Users	The total number of active MAC authentication users.

Table describes the default dashboard charts.

Dashboard Chart	Description
Authentication Success	The number of successful authentications over the selected time (1, 7, or 30 days). The 7-day chart is a bar graph. The 1-day and 30-day charts are line graphs.
Authentication Failure	The number of failed authentications over the selected time (1, 7, or 30 days). The 7-day chart is a bar graph. The 1-day and 30-day charts are line graphs.
Session OS Count	Pie chart showing the number of the sessions per operating system.
Top Roles	Pie chart showing the number of top user roles assigned during the selected time.
Compliance Results	Pie chart showing Host Checker posture assessment results: Compliant, Not Compliant, Not Assessed, or Remediated. Compliance results are reported for all instances in which Host Checker is run. The posture assessment chart is clubbed with the compliance results chart for IPS. To view the posture assessment chart, select Posture Assessment from the dropdown list.
Posture Assessment	Pie chart showing Host Checker policy violations. Policy violations are reported only for instances in which Host Checker is run at initial sign in.
Auth Mechanism	Pie chart showing the number of sessions per authentication mechanism: 802.1x, Layer 3, MAC address. It applies to IPS only.

Dashboard Database

The dashboard monitoring service collects and stores data in a database for 30 days. The total number of records stored in the database can be up to 300,000 records.

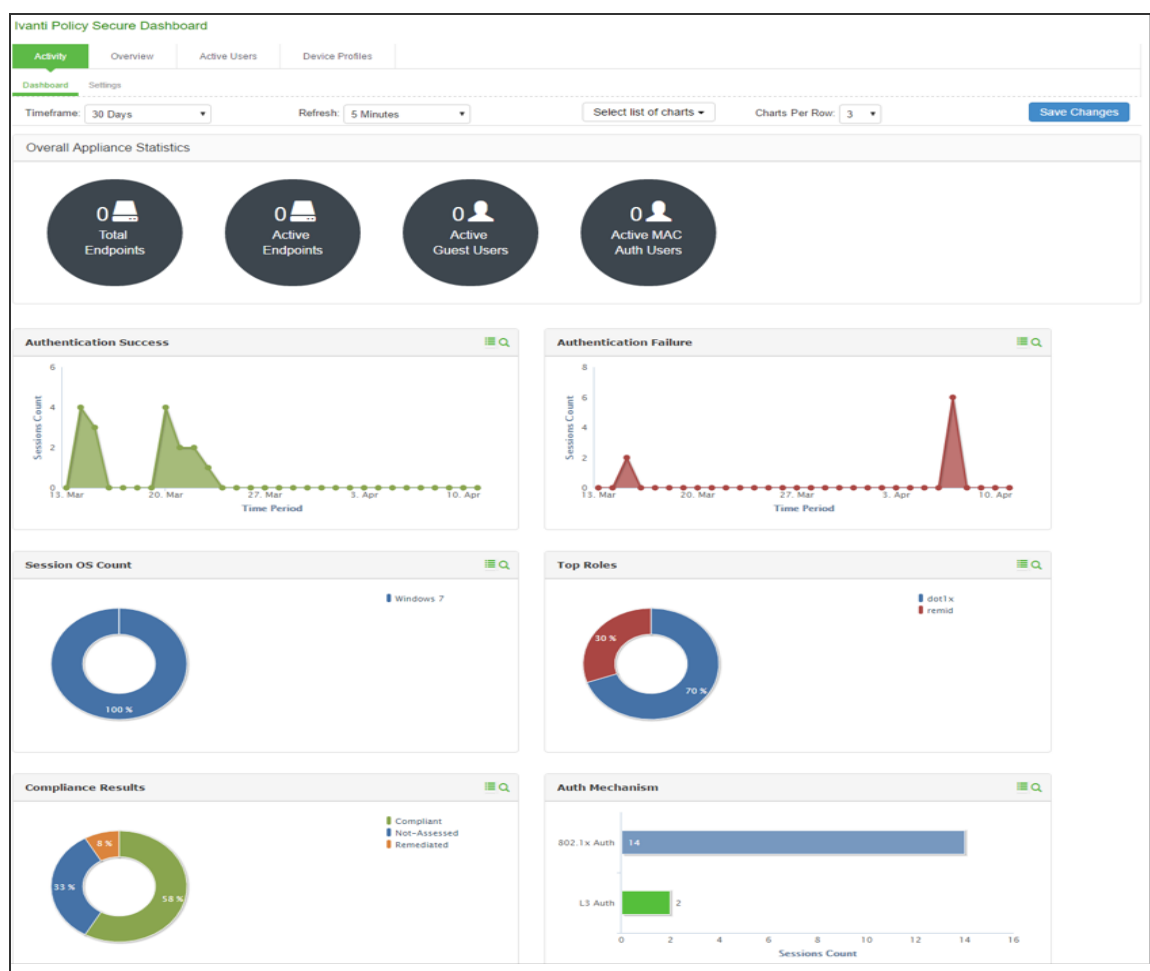

The dashboard database is created only after upgrading to IPS version 5.0 or later and enabling the dashboard option. Note that only new sessions are added to the database and changing the Time Frame filter or clicking refresh sends queries to the database. The data is collected only when the dashboard option is enabled.

Table describes the different actions and their results.

Action	Description
Disable and then reenble the dashboard.	The data collection stops when your dashboard is disabled.
Restore the data from backup, snapshot, or import config.	The data is not exported and the data is retained during upgrades

Displaying the Dashboard

To display the dashboard, select **System > Status > Activity > Dashboard**.

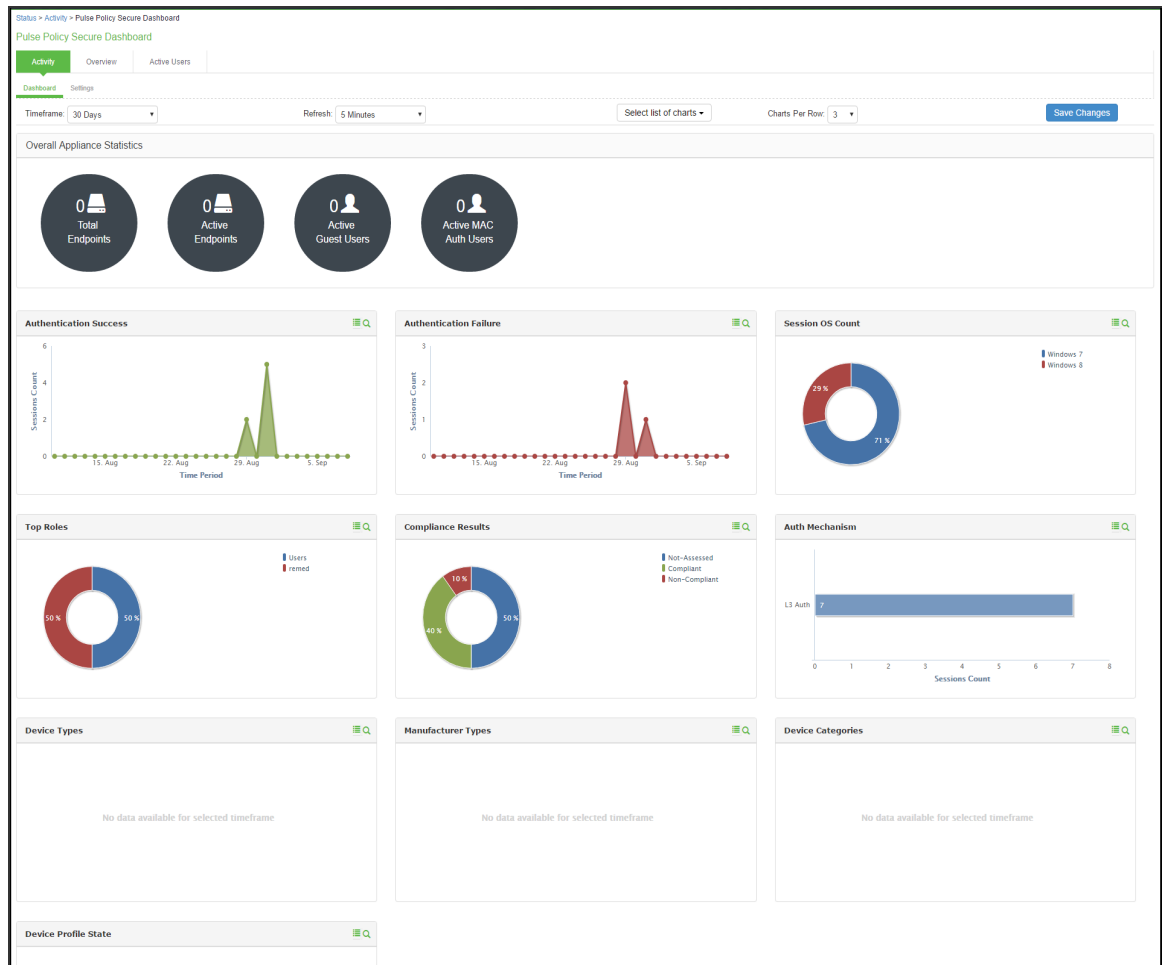

Selecting a Data Time Frame

To select a data timeframe:

1. Select **System > Status > Activity > Dashboard**.
2. Select one of the following periods from the Time Frame list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.

Access records are kept for 30 days. Older records are removed and not included in dashboard charts and reports.

Refreshing Data

To refresh data:

1. Select **System > Status > Activity > Dashboard**.
2. Select one of the following refresh rates from the Refresh list box:
 - Disabled
 - 5 Minutes
 - 10 Minutes
 - 30 Minutes
 - 60 Minutes

Drilling Down to Detailed Reports

To drill down to view detailed reports:

1. Select **System > Status > Activity > Dashboard**.
2. Click the search icon to display the corresponding tabular report with predefined search filters.
For example, enter the filter criteria with the Authentication Results set to Success.

Schedule Report or Email Scheduling

IPS allows you to schedule email notification for sending customized reports. Admin can configure email frequency and select one of the saved filters for getting a customized report.

To schedule reports:

1. Select **System > Configuration > Notification > Email Scheduler** or **Schedule report** option in the reports page.
2. Enter the name for the email schedule rule.
3. Under Email Settings, enter the email address either from **General Settings** or **Custom** option.
4. Click **Test Settings** to test the email settings.

5. Configure the email schedule frequency for running the email schedule.
 - **Daily** – Generates reports daily at a specified time.
 - **Weekly** – Generates reports every Monday at a specified time.
 - **Monthly** – Generates reports on 1st of every month at a specified time.
 - **Custom** – Generates reports based on date and time.
6. Under **Report Settings**, select the report type from the drop-down.
7. If Device Discovery Report is selected, the following 2 options appear.
 - **Generate Full Report**- If selected, full (stats) report is generated rather than incremental report. If unselected, Incremental reports are generated based on the email schedule. For example, if Weekly is selected, the reports will be generated based on the last one week activity on the Profiler.
 - **Generate Device Discovery Report**- If selected a filter drop-box appears. Device Discovery Report is generated along with the Profiler statistics in PDF format. If unselected, only Profiler statistics will be sent.
8. Choose the desired filter. See [Creating a new Filter](#) section for information on how to create filters. The corresponding saved filters gets populated automatically.
9. Click **Save Changes**.

The newly created email rule gets listed in the email rules table. The reports will be generated based on the selection and emailed. The existing email schedule can also be edited or deleted based on your requirement.

The scheduled email reports will be sent based on IPS server time.
Only one email schedule can be configured for one report at a time.

Using the User Summary Report

This topic describes the user summary report. It includes the following information:

Overview

The user summary report displays user statistics such as realm, username, last log in time, last log in IP, successful log in, and so on for each user based on the user activity in the selected time range.

To display the user summary report, select **System > Reports > User Summary**.

Reports > User Summary Report

Username	Realm	Last Login Time	Last Login IP	Login Success	Login Failure	Compliant Sessions	Non-Compliant Sessions	Remediated Sessions	Total Session Length	Average Session Length
shr1	Users	Tue Feb 02 08:26:27 2021	10.204.90.86	1	2	1	1	0	5h 2m 13s	5h 2m 13s
shr2	Users	Tue Feb 02 08:25:56 2021	10.204.90.86	0	1	0	0	0	0m 0s	0m 0s

Table describes the columns on the user summary report.

Column	Description
Username	Specifies the name of the user.
Realm	Specifies the realm.
Last Login Time	Specifies the last time the user logged in.
Last Login IP	Specifies the last IP that the user logged in with.
Login Success	Specifies the number of successful log ins.

Column	Description
Login Failure	Specifies the number of failed log ins.
Compliant Sessions	Specifies the number of compliant sessions.
Non Compliant Sessions	Specifies the number of non compliant sessions.
Remediated Sessions	Specifies the number of remediated sessions.
Total Session Length	Specifies the total length of the sessions.
Average Session Length	Specifies the average length of the sessions.

Creating a new Filter

To create a new filter:

1. Select **System > Reports > User Summary**.
2. Under Filter, enter the name of the filter.
3. Under Filter by: Select one of the following periods from the Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.
4. Enter search criteria in one or more of the following attribute columns:
 - Username
 - Realm

5. Click **Save Filter**.

Once the filter is created, it gets listed in the filter drop-down. Administrator can also choose to edit the existing filter to customize the report based on the requirement. The filter can also be deleted using the Delete Filter option.

Applying Data Filters

To apply a data filter:

1. Select **System > Reports > User Summary**.
2. Select one of the following periods from the Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.
3. Enter search criteria in one or more of the following attribute columns:
 - Username
 - Realm
4. Click **Apply Filter**.

Sorting Records

The data source determines the default sort order of the data rows in the report. Typically, data appears randomly, so sorting is an important task in creating a useful report. You can sort single data columns or multiple columns.

To sort the user summary report

1. Select **System > Reports > User Summary**.
2. Select one of the following columns from the user summary report table and click either the ascending or descending order icon.
 - Username
 - Realm
 - Last Login Time

The username column is sorted in ascending order by default.

Drilling Down to the Single User Report

To drill down to a single user report:

1. Select **System > Reports > Single User Activities**.
2. Enter the username and specify the data range.
3. Click **Apply Filter**.

Exporting User Summary Report

To export device summary report:

1. Select **System > Reports > User Summary**.
2. Select a Download Report option.
 - **CSV**– Exports the report in CSV format.
 - **Tab Delimited**– Exports the report in tab-delimited format.
 - **PDF**– Exports the report in PDF format.

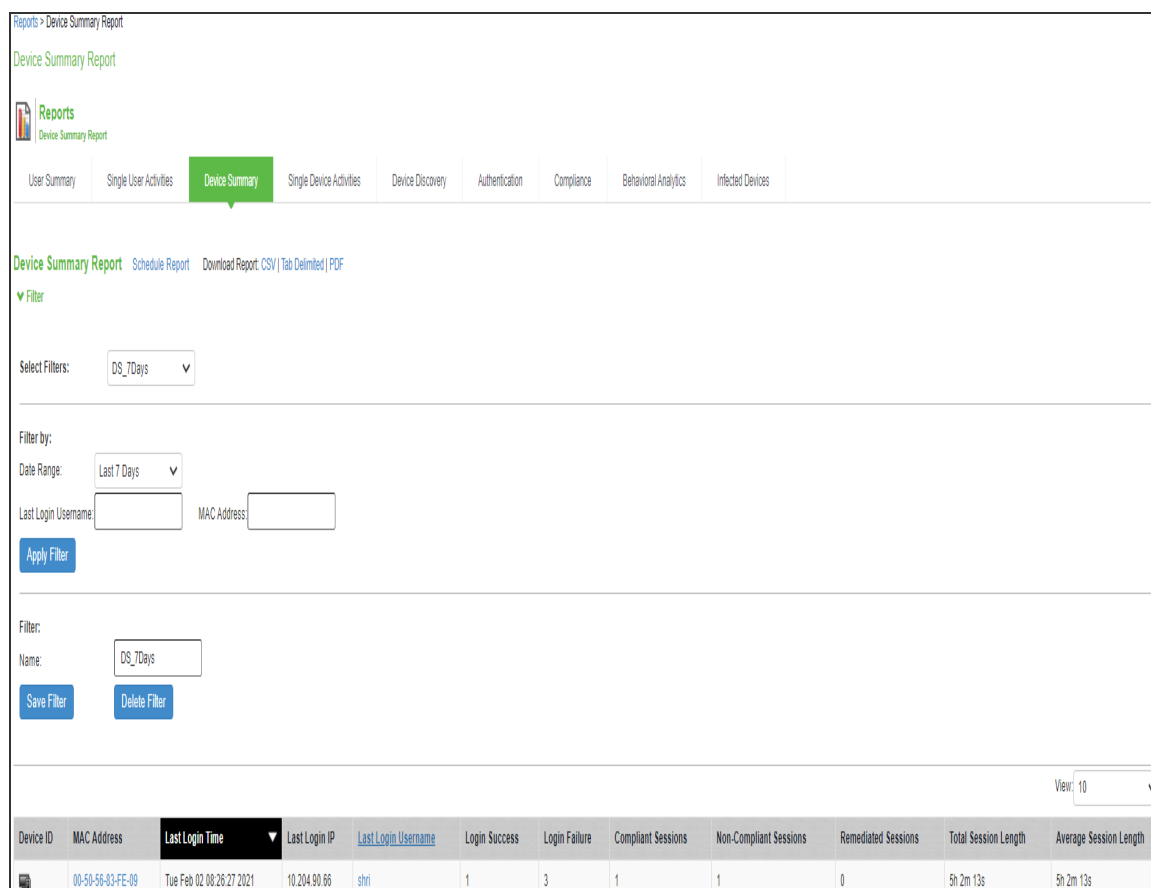

Using the Device Summary Report

This topic describes the device summary report.

Overview

The device summary report displays device information such as device detail, MAC address, last log in time, last log in IP, log in successful, and so on for each user based on device activity in the selected time range.

To display the device summary report select **System > Reports > Device Summary**.

The following table describes the columns on the device summary report.

Column	Description
Device ID	Specifies a unique identifier to identify the endpoint. Click the device ID icon to view a single device report.
MAC Address	Specifies the MAC address of the device. Click the MAC address to view a single device report.

Column	Description
Last Login Time	Specifies the last time the device was logged in.
Last Login IP	Specifies the last IP that the device logged in with.
Last Login Username	Specifies the username that the user logged in with.
Login Success	Specifies the number of successfully log ins.
Login Failure	Specifies the number of failed log ins.
Compliant Sessions	Specifies the number of compliant sessions.
Non-Compliant Sessions	Specifies the number of non-compliant sessions.
Remediated Sessions	Specifies the number of remediated sessions.
Total Session Length	Specifies the total session length.
Average Session Length	Specifies the average session length.

If a device has more than one MAC address in a session, then the value appearing in the MAC Address column will be multiple instead of the actual MAC addresses. Note that the value multiple is not hyperlinked.

Creating a new Filter

To create a new filter:

1. Select **System > Reports > User Summary**.
2. Under Filter, enter the name of the filter.

3. Under Filter by: Select one of the following periods from the Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.
4. Enter search criteria in one or more of the following attribute columns:
 - Last Login Username
 - Mac Address
5. Click **Save Filter**.

Once the filter is created, it gets listed in the filter drop-down. Administrator can also choose to edit the existing filter to customize the report based on the requirement. The filter can also be deleted using the Delete Filter option.

Applying Data Filters

To apply a data filter:

1. Select **System > Reports > Device Summary**.
2. Select one of the following periods from the Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.
3. Enter search criteria in one or more of the following columns:
 - Last Login Username
 - Mac Address
4. Click **Apply Filter**.

Sorting Records

The data source determines the default sort order of the data rows in the report. Typically, data appears randomly, so sorting is an important task in creating a useful report. You can sort single data columns or multiple columns.

To sort the device summary report

1. Select **System > Reports > Device Summary**.
2. Select any one of the following column and click either the ascending or descending order icon.
 - Last Login Time
 - Last Login Username

You can sort the column in either ascending order or descending order.

Exporting Device Summary Report

To export device summary report:

1. Select **System > Reports > Device Summary**.
2. Select a Download Report option.
 - **CSV**– Exports the report in CSV format.
 - **Tab Delimited**– Exports the report in tab-delimited format.
 - **PDF**– Exports the report in PDF format.

Using the Single Device Report

This topic describes the single device report.

Overview

The single device activities report displays the device activity information such as username, realm, log in time, log out time, device detail, MAC address, authentication mechanism, authentication result, compliance, IP address, role and so on for each device.

To display the single device activities report, select **System > Reports > Single Device Activities**.

Table describes the columns on the single device report.

Column	Description
Username	Specifies the name of the user.
Realm	Specifies the realm.
Login Time	Specifies the time the user logged in.
Logout Time	Specifies the time the user logged out.
Duration	Specifies the total duration of the user session.
Device ID	Specifies a unique identifier used to identify an end point. Click the device ID icon to view a single device report.

Column	Description
MAC Address	Specifies the MAC address of the device.
Auth Mechanism	Specifies the authentication mechanism: 802.1x, Layer 3, MAC address.
Auth Result	Specifies the authentication result.
Compliance	Specifies the Host Checker posture assessment results: Compliant, Not Compliant, Not Assessed, or Remediated.
IP Address	Specifies the IP that the user logged in with.
Role	Specifies the role of the user.
Device Detail	Displays the URL that is used for connecting to the MDM server.

Creating a new Filter

To create a new filter:

1. Select **System > Reports > User Summary**.
2. Under Filter, enter the name of the filter.
3. Under Filter by: Select one of the following periods from the Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.

4. Enter search criteria in one or more of the following attribute columns:

- Compliance Results
- MAC Address
- Device ID
- Authentication Mechanism (L3 Auth, 802.1X Auth, MAC auth, all)

5. Click **Save Filter**.

Once the filter is created, it gets listed in the filter drop-down. Administrator can also choose to edit the existing filter to customize the report based on the requirement. The filter can also be deleted using the Delete Filter option.

Applying Data Filters

To apply a data filter:

1. Select **System > Reports > Single Device Activities**.
2. Select one of the following periods from the Filter by: Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.
3. Enter search criteria in one or more of the following columns:
 - Compliance Results
 - MAC Address
 - Device ID
 - Authentication Mechanism (L3 Auth, 802.1X Auth, MAC auth, all)
4. Click **Apply Filter**.

Sorting Records

The data source determines the default sort order of the data rows in the report. Typically, data appears randomly, so sorting is an important task in creating a useful report. You can sort single data column.

To sort the single device activities report:

1. Select **System > Reports > Single Device Activities**.
2. Select Login Time column and click either the ascending or descending order icon.
3. You can sort the column in either ascending order or descending order.

Exporting Single Device Activities Report

To export single device activities report:

1. Select **System > Reports > Single Device Activities**.
2. Select a Download Report option.
 - **CSV**– Exports the report in CSV format.
 - **Tab Delimited**– Exports the report in tab-delimited format.
 - **PDF**– Exports the report in PDF format.

Using the Device Discovery Report

You can view the device discovery report if you have integrated Profiler with IPS. The Device Discovery Report contains the list of devices that are discovered in the network. Select **System > Reports > Device Discovery** to view the report.

Reports > Device Discovery Report

Reports

Table describes the columns on the authentication report.

Column	Description
Username	Specifies the name of the user.
Realm	Specifies the realm.
Login Time	Specifies the time the user logged in.
Auth Mechanism	Specifies the authentication mechanism: 802.1x, Layer 3, MAC address.
Auth Result	Specifies the authentication result.
Failure Reason	Specifies the host checker failure reason.

Column	Description
Device ID	Specifies a unique identifier used to identify an end point. Click the device ID icon to view a single device report.
Role	Specifies the user role.
Device OS	Specifies the operating system of the device.
IP Address	Specifies the IP Address of the device.
MAC Address	Specifies the MAC Address of the device.

The Authentication Report in the dashboard database has a maximum limit of 300K records. After this limit, the oldest records are removed.

Creating a new Filter

To create a new filter:

1. Select **System > Reports > User Summary**.
2. Under Filter, enter the name of the filter.
3. Under Filter by: Select one of the following periods from the Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.

4. Enter search criteria in one or more of the following attribute columns:

- Authentication Mechanism
- Authentication Results
- Username
- Realm
- IP Address
- Mac Address
- Roles

5. Click **Save Filter**.

Once the filter is created, it gets listed in the filter drop-down. Administrator can also choose to edit the existing filter to customize the report based on the requirement. The filter can also be deleted using the Delete Filter option.

Applying Data Filters

To apply a data filter:

1. Select **System > Reports > Authentication**.
2. Select one of the following periods from the Filter by: Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.

3. Enter search criteria in one or more of the following columns:

- Authentication Mechanism
- Authentication Results
- Username
- Realm
- IP Address
- Mac Address
- Roles

4. Click **Apply Filter**.

Sorting Records

The data source determines the default sort order of the data rows in the report. Typically, data appears randomly, so sorting is an important task in creating a useful report. You can sort single data column.

To sort the authentication report:

1. Select **System > Reports > Authentication**.
2. Select **Login Time column** and click either the ascending or descending order icon.

Exporting Authentication Report

To export an authentication report:

1. Select **System > Reports > Authentication**.
2. Select a Download Report option.
 - **CSV**– Exports the report in CSV format.
 - **Tab Delimited**– Exports the report in tab-delimited format.
 - **PDF**– Exports the report in PDF format.

Using the Compliance Report

This topic describes the compliance report.

Overview

The compliance report displays compliance status such as compliant, not compliant, remediated, not assessed information for each user based on the device activity in the selected time range.

To display the compliance report, select **System > Reports > Compliance**.

Type	Failure Reason
HC	HDEncryption software not installed Detected Unencrypted drives Drives are missing Unsupported client for HDEncryption check Patch Management software not installed Detected missing patches Unsupported client for PatchMgmt check Deprecated patch assessment rule

Creating a new Filter

To create a new filter:

1. Select **System > Reports > User Summary**.
2. Under Filter, enter the name of the filter.
3. Under Filter by: Select one of the following periods from the Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.
4. Enter search criteria in one or more of the following attribute columns:
 - Compliance Results
 - Username
 - Realm
 - MAC Address
5. Click **Save Filter**.

Once the filter is created, it gets listed in the filter drop-down. Administrator can also choose to edit the existing filter to customize the report based on the requirement. The filter can also be deleted using the Delete Filter option.

Applying Data Filters

To apply a data filter:

1. Select **System > Reports > Compliance**.
2. Select one of the following periods from the Filter by: Date Range list box:
 - **Last 24 Hours**– (Default) Refers to the last 24 hours from the current hour.
 - **Last 7 Days**– Refers to current day and the previous last 6 days.
 - **Last 30 Days**– Refers to current day and the previous last 29 days.
 - **Custom**– Enter the custom from and till date range.
3. Enter search criteria in one or more of the following columns:
 - Compliance Results
 - Username
 - Realm
 - MAC Address
4. Click **Apply Filter**.

Sorting Records

The data source determines the default sort order of the data rows in the report. Typically, data appears randomly, so sorting is an important task in creating a useful report. You can sort single data column.

To sort the compliance report:

1. Select **System > Reports > Compliance**.
2. Select **Initial Host Check Time** or Username column and click either the ascending or descending order icon.

Exporting Compliance Report

To export a compliance report:

1. Select **System > Reports > Compliance**.
2. Select a Download Report option.
 - **CSV**– Exports the report in CSV format.
 - **Tab Delimited**– Exports the report in tab-delimited format.
 - **PDF**– Exports the report in PDF format.

Using the Infected Devices Report

This topic describes the infected devices report.

Overview

The infected devices report displays infected device details such as MAC address, user name, IP address, device status information.

To display the compliance report, select **System > Reports > Infected Devices**.

 - MAC Address
5. Click **Save Filter**.

Once the filter is created, it gets listed in the filter drop-down. Administrator can also choose to edit the existing filter to customize the report based on the requirement. The filter can also be deleted using the Delete Filter option.

Exporting Infected Devices Report

To export a infected device report:

1. Select **System > Reports > Infected Devices**.
2. Select a Download Report option.
 - **CSV**– Exports the report in CSV format.
 - **Tab Delimited**– Exports the report in tab-delimited format.
 - **PDF**– Exports the report in PDF format.

System Maintenance

Overview

The system maintenance operations must be planned to ensure that your system functions properly and to avoid any network disruptions. You can check the IPS platform information and perform the required tasks, which includes upgrading or downgrading the software, downloading the client installer files, performing disk cleanup operations and so on.

The system maintenance menu includes the following components:

- Platform- Use this option to check the platform information such as model, version, serial number, current version, and the rollback version. This helps the Administrator to perform/plan any routine system maintenance operations.
- Upgrade/Downgrade- Use this option to upgrade/downgrade the IPS software.
- Change Personality- Use this option to change the personality of the IPS device to a ICS device.
- Options- Use this option to check the global system parameters, including hardware settings.
- Installers- Use this option to download the client installer files based on the user platform.

Configuring System Platform

The platform page provides a quick overview of the current state of the system. This gives a quick overview of what Operation System the system has booted, the fallback version, host name, hardware model, serial number, uptime, current version, and the rollback version.

System Maintenance > Platform

Platform

Platform Upgrade/Downgrade Change Personality Options Installers

Hostname: isahw54
Model: ISA-8000c
Machine ID: 0482MXH8A0Q2U1V8E
Serial Number: 0482102021100346
Uptime: 1 hour, 41 minutes, 31 seconds
Current version: 22.2R3 (build 973)
Rollback version: 22.1R1 (build 211)

Node operations: Restart Services Reboot... Shut Down... Rollback...

Connectivity:
 This will ping various configured servers to test the device's connectivity. Test Connectivity

To restart, reboot, rollback or shut down the system:

1. Select **Maintenance > System > Platform** to display the system maintenance platform page.
2. Click the desired node operation:
 - **Restart**—Kills all processes and restarts the system. The system is available again after a few minutes.
 - **Reboot**—Power cycles and reboots the system. The system is available again after a few minutes.
 - **Shut Down**—Shuts down the system. The system is not available again until the physical power button on the physical device is used to restart the system.
 - **Rollback**—The system is rolled back to the previous software version and configuration state. The system is rebooted and unavailable for a few minutes when you rollback.

- The restart, reboot, and shutdown operations are applied to all enabled members of a cluster. If you do not want to apply the operations to all members of the cluster, use the System > Clustering > Status page to disable members; then perform the restart, reboot, or shut down operation.

- If you have enabled logging for Administrator changes (System > Log/Monitoring > Admin Access > Settings page), a log is written to the Admin Access logs page. If you have enabled logging for System Status (System > Log/Monitoring > Events > Settings page), logs are written to the Events logs page.

Configuring System Maintenance Options

You can use the maintenance options page to enable various system maintenance features.

To enable various system maintenance features:

1. Select **Maintenance > System > Options** to display the maintenance options page.
2. Select options as described in table.
3. Save the configuration.

System Maintenance > Options

Options

Platform Upgrade/Downgrade Change Personality Options Installers

☒ Automatic version monitoring

By enabling this feature, you allow the retention of any data regarding usage and performance statistics to be used by Pulse Secure, including for improvement of future versions of the product and related support. The data is transmitted over a secure (SSL) connection.

☐ Enable gzip compression

Use gzip compression to reduce the amount of data sent to browsers that support HTTP compression. This can result in faster page downloads for some users.

☐ Enable Kernel Watchdog

Enables the kernel watchdog that automatically restarts the system under kernel deadlock or when kernel runs low on some key resources.

☒ Enable File System Auto-clean Feature

Enables the system to automatically clean up the file system when disk utilization reaches 90%. IMPORTANT: when enabled, this feature may result in loss of data that may be relevant in debugging system problems that occurred a week or earlier in the past (i.e. old debuglogs, core files, and snapshots may be removed.)

☒ Enable web installation and automatic upgrade of Odyssey Access Clients

☒ Enable web installation and automatic upgrade of Pulse Secure clients

By default, the Policy Secure automatically installs and upgrades UAC agents (Odyssey or Pulse clients) of users who have connected to it. These options can be used to enable/disable the automatic installation and upgrade of the UAC agent. Uncheck this option only if you intend to manage installation and upgrade of the UAC agent through some other mechanism (for more information, refer to the documentation).

End-user Localization: Automatic (based on browser settings) ▼

▶ External User Records Management

Save Changes

Options	Guidelines
Automatic version monitoring	<p>If you enable this option, the system reports the following data to IPS:</p> <ul style="list-style-type: none"> Machine identifier. Information describing your current software, including: <ul style="list-style-type: none"> Software build number and build name. An MD5 hash of your license settings. An MD5 hash of the internal interface IP address. If this node is in a cluster, the number of nodes within that cluster. Current state of the node. Cluster type (active/active, active/passive). Total number of unique subnets on the cluster nodes. Version of Ivanti Policy Secure. Version of ESAP. Cluster log synchronization status. Number of Infranet Enforcers configured Names of RADIUS vendors configured Total number of concurrent users on the device. <p>We strongly recommend that you enable this service.</p>
Kernel Watchdog	<p>Enables the kernel watchdog that automatically restarts the system under kernel deadlock or when kernel runs low on some key resources.</p> <hr/> <div data-bbox="472 1518 521 1570"></div> <p>Enable the kernel watchdog only when instructed by Ivanti Global Support Center.</p> <hr/>
File System Auto-clean	<p>Enables the system to automatically clean up the file system when disk utilization reaches 90%.</p>

Options	Guidelines
	<div>  <p>The clean-up operation deletes files that might be relevant in debugging—for example, debug logs, core files, and snapshots might be deleted.</p> </div>
Web installation and automatic upgrade of Ivanti Secure Access Client	<p>After you deploy Ivanti Secure Access Client software to endpoints, software updates occur automatically. A Ivanti Secure Access Client can receive updates from the server. If you upgrade the software on your server, updated software components are pushed to a client the next time it connects.</p> <p>A bound endpoint receives connection set options and connections from its binding server, but it can have its Ivanti Secure Access Client software upgraded from any server that has the automatic upgrade option enabled. During a client software upgrade the client loses connectivity temporarily.</p>
Virtual Terminal console	Enables the virtual terminal on a virtual appliance. Clear this check box to use the serial console. Changing this setting will restart the system.
End-user Localization	<p>Select one of the following options:</p> <ul style="list-style-type: none"> Automatic (based on browser settings) English (U.S.) Chinese (Simplified) Chinese (Traditional) French German Japanese Korean Spanish
External User Records Management	
Persistent user records limit	Specify the maximum number of user records.

Options	Guidelines
	This feature is useful when system performance is affected due to many user records. We highly recommend you consult Ivanti Global Support Center prior to using this feature. Deleting a user record removes all persistent cookies, SSO information, and other resources for that user. It does not remove the user record from the external or internal authentication server. If you delete a user record and that user logs back in to the authentication server, new user records are created. Records are not removed if that user is currently logged in.
Number of records to delete when the limit is exceeded	Specify a number. Older records are removed first. A user record is not deleted if that user is currently logged in.
Delete records now	Check whether the persistent user records limit has been exceeded. If it is, delete the number of user records specified in the option above.
Automatic deletion of user records during new user log ins	Check whether the persistent user records limit will be exceeded whenever a new user record is about to be created. If true, delete the records prior to creating the user new record.

Installing the Service Package

This topic describes how to upgrade, downgrade, and rollback the system software.

Downloading and Uploading the Software Package

To download a software package:

1. Go to https://forums.ivanti.com/s/product-downloads?language=en_US and browse to the software download page for your product.
2. When prompted, log in with your Ivanti customer username and password.

3. Accept the license agreement.
4. When prompted, save the software package to your local host.

You can upload a software package to the system without immediately initiating the upgrade process. This is known as staging the upgrade. You can stage one package. Uploading a second package overwrites the previous staging.

To upload a software package:

1. Select **Maintenance > System > Upgrade/Downgrade** to display the system software maintenance page.
2. Under Managed Staged Service Package, select Upload new package into staging area and use the Browse button to locate and select the service package file.
3. Click **Submit** to upload the file.

The Upload Status window shows the progress of the upload operation.

System Maintenance > Install Service Package

Install Service Package

Platform Upgrade/Downgrade Change Personality Options Installers

Installing a service package can take several minutes and requires the system to reboot. Because existing system data is backed up during this process, you can decrease installation time by clearing your [system log](#) before trying to install a service package.

Note: Browsing away from this page while uploading the package will abort the installation.

▼ Install Service Package

☐ From File

No file chosen

☐ From Staged Package

Choose this option if you want to install the staged service package.

☐ DELETES all system and user configuration data before installing the service package, restoring the member to an unconfigured state. Use this option if you want to downgrade to an older service package than the currently installed package. Do NOT check this box if you want to retain existing settings and data during a system upgrade to a newer service package.

Note: This option does not change the factory image.

▼ Manage Staged Service Package

☐ Upload new package into staging area

No file chosen

☐ Delete Staged Package

If you have enabled logging for Administrator changes (**System > Log/Monitoring > Admin Access > Settings** page), a log is written to the Admin Access logs page.

Upgrading the System Software

Installing a service package can take several minutes and requires the system to reboot. Because existing system data is backed up during this process, you can decrease installation time by clearing your system log before trying to install a service package.

- When the system software is upgraded the latest set of updated Trusted Server CAs are uploaded. These new set of Trusted Server CAs can be seen in the **System > Configuration > Certificates > Trusted Server CAs** page. The expired certificates are removed from the system.
 - When the system software is upgraded, it automatically upgrades IPS to OpenSSL version 1.0.2n.
-

To upgrade the operating system:

1. Select **Maintenance > System > Upgrade/Downgrade** to display the system software maintenance page.
 2. Under Install Service Package, select one of the following options to proceed:
 - **From File**—Use the Browse button to locate and select the service package file.
 - **From Staged Package**—Select the service package file that was previously uploaded.
-

Do not select the **Deletes** option when you are upgrading software. The Deletes option is available to support downgrading software.

3. Click **Install**.

The system displays the Service Package Installation Status page, which provides a summary of the integrity checks and compatibility checks and other status indicators.

Service Package Installation Status

The installation process takes a few minutes. When complete, the system needs to reboot. Please wait...

- Step 1: Verifying package integrity complete (32 seconds)
- Step 2: Extracting install script complete (43 seconds)
- Step 3: Extracting install script complete (14 seconds)
- Step 4: Preparing disk partitions complete (1 seconds)
- Step 5: Extracting contents of new package complete (14 seconds)
- Step 6: Saving package complete (14 seconds)
- Step 7: Finalizing installation complete (23 seconds)
- Step 8: Encrypting drive please wait complete (96 seconds)
- Step 9: Switching current system to "rollback" and enabling new system ... complete (1 seconds)

🟢 Installation completed successfully and the system will now reboot.: Note that the Administrator Console will be unavailable while the system reboots.(Watch the serial console for messages).

When the system reboots click [here](#) to continue using the Administrator Console.

If you have enabled logging for Administrator changes (**System > Log/Monitoring > Admin Access > Settings page**), a log is written to the **Admin Access** logs page. If you have enabled logging for System Status (System > Log/Monitoring > Events > Settings page), logs are written to the Events logs page.

Downgrading the System Software

If necessary, you can downgrade to an earlier version of the system software. When you downgrade, you must clear the system and configuration data to avoid unexpected behavior that can occur when the system has data that relates to the newer software.

If you downgrade the system, you must reestablish network connectivity before you can reconfigure it.

To downgrade the operating system:

1. Select **Maintenance > System > Upgrade/Downgrade** to display the system software maintenance page.
2. Under Install Service Package, select one of the following options to proceed:
 - **From File**—Use the Browse button to locate and select the service package file.
 - **From Staged Package**—Select a service package file that was previously uploaded.
3. Select the Deletes all system and user configuration data option to delete all system and user configuration data before installing the service package, restoring the member to an unconfigured state.
4. Click **Install**.

Changing the Device Personality

You can use this page to change the device's personality from IPS to ICS. You must perform a backup operation to avoid losing the configuration data before using this configuration.

To change the device personality:

1. Click **Browse** and select the **ICS service package to install**.
2. Click **Change Now**.

System Maintenance > Change Personality

Change Personality

Platform Upgrade/Downgrade **Change Personality** Options Installers

Changes the device's personality from Pulse Policy Secure to Pulse Connect Secure. Please make sure you provide the Pulse Connect Secure package to install. This operation will **DELETE** all configuration data before installing the service package, restoring the member to an unconfigured state. **Please backup the configuration** before you perform this operation.

Note: This option does not change the factory image.

Service package to install: package.pkg

Downloading Client Installer Files

You can use the system maintenance client installers page to download client installer files. The downloadable files include .exe and .msi files for use installing clients on Windows platforms, and .dmg files for installing clients on Macintosh platforms.

To download client installer files:

1. Select **Maintenance > System > Installers** to display the client installer files page.
2. Click **Download** to download the file to your local host.

The screenshot shows the 'System Maintenance > Installers' page. At the top, there is a breadcrumb trail 'System Maintenance > Installers' and a tab labeled 'Installers'. Below the tab, there is a list of client installer files with icons and descriptions:

- Pulse Secure Installer Service (.exe)**: This component simplifies future installation and upgrades of Ivanti Secure Access Client for users with limited desktop privileges. Use this self-extracting .exe package unless a specific requirement exists for Microsoft Windows Installer (msi) packages. This package can be deployed with limited user privileges if a previous version of the Installer Service is running.
- Pulse Secure Installer Service (.msi)**: This component simplifies future installation and upgrades of Ivanti Secure Access Client for users with limited desktop privileges. Deploy this Microsoft Windows Installer (msi) package if your organization or infrastructure requires msi packages. One such example would be automated software installation using Microsoft Systems Management Server.
- Host Checker**: This component verifies security settings on user's workstation.
- Third-party Integrity Measurement Verifier (IMV) Server**: This component allows third-party integrity measurement verifiers (IMV's) to be used with the Ivanti Policy Secure.
- Ivanti Secure Access Client Installer (Windows 32-bit)**: This setup application installs all Ivanti Secure Access Client components. Please consult the Ivanti Secure Access Client Supported Platforms Guide for this version to determine which versions of Windows 32-bit client operating systems are supported.
- Ivanti Secure Access Client Installer (Windows 64-bit)**: This setup application installs all Ivanti Secure Access Client components. Please consult the Ivanti Secure Access Client Supported Platforms Guide for this version to determine which versions of Windows 64-bit client operating systems are supported.
- Ivanti Secure Access Client Installer (ARM 64-bit)**: This setup application installs all Ivanti Secure Access Client components. Please consult the Ivanti Secure Access Client Supported Platforms Guide for this version to determine which versions of ARM 64-bit processor supported.
- Ivanti Secure Access Client Installer (MacOS)**: This setup application installs all Ivanti Secure Access Client components. Please consult the Ivanti Secure Access Client Supported Platforms Guide for this version to determine which versions of MacOS client operating systems are supported.
- Pulse Application Launcher Installer**: This setup application installs all Pulse Application Launcher components.
- Pulse Application Launcher Installer (MacOS)**: This setup application installs all Pulse Application Launcher components.
- Pulse Application Launcher Installer (Linux)**: This setup application installs all Pulse Application Launcher components.

Testing Network Connectivity

You can use the admin console to test network connectivity to all the servers with which the system is configured to communicate, for example network services or AAA servers.

To test network connectivity:

1. Select **Maintenance > System > Platform** to display the system maintenance platform page.
2. Click **Test Connectivity**.

The screenshot displays the 'System Maintenance > Platform' page. At the top, there is a navigation bar with tabs: Platform (selected), Upgrade/Downgrade, Change Personality, Options, and Installers. Below the navigation bar, the main content area shows the following information:

- Node Information:** Hostname: localhost2, Model: PSA-3000, Serial Number: 0312122015100079, Uptime: 10 days, 1 hour, 47 minutes, 59 seconds, Current version: 5.3RS (build 38279), Rollback version: 5.2R7 (build 36297).
- Node operations:** Restart Services, Reboot..., Shut Down..., Rollback...
- Connectivity:** This will ping various configured servers to test the device's connectivity. A 'Test Connectivity' button is present.
- Hardware Status:** A section with a green checkmark icon.
- Fan Status:** A table showing the status of the fans.

Fan	Status
2	0

Server connectivity results

i	Destination host 10.96.64.1 used as Gateway Address is responding.
i	Destination host 10.204.91.73 used as DNS Server is responding.
i	Destination host ege used as LDAP Server is not responding to icmp ping requests.
i	Destination host apidev-as.aumdm.com used as MDM Server is responding.
i	Destination host m.mobileiron.net used as MDM Server is not responding to icmp ping requests.

Logging and Monitoring

Logging Overview

Ivanti Policy Secure(IPS) provides logging and monitoring capabilities to help you track events and user activities. The system generates event logs related to system performance, administrator actions, network communications, access management framework results, user sessions, and so forth.

The available logs, includes:

- **Event Logs-** This file contains a variety of system events, such as session timeouts, systems errors and warnings, server restart notifications and connectivity requests.
- **User Access Logs-** This file contains information about when the user access the appliance, time, number of simultaneous users, user sign-ins and sign-outs.
- **Admin Access Logs-** This file contains administration information, including administrator changes to user, system and network settings, such as changes to session timeouts, license changes and so on.

The system supports the following log collection methods:

- Local log collector and log viewer.
- Reporting to syslog servers.
- Reporting to SNMP servers.

The following table describes the event log severity levels.

Severity Level	Description
Critical	The system cannot serve user and administrator requests or loses functionality to a majority of subsystems.
Major	The system loses functionality in one or more subsystems, but users can still access the system for other access mechanisms.
Minor	The system encounters an error that does not correspond to a major failure in a subsystem. Minor events generally correspond to individual request failures.

Severity Level	Description
Info	The system writes an informational event to the log when a user makes a request or when an administrator makes a modification.

In addition to managing system logs, you can use the admin console to configure collection of client-side logs, including Host Checker logs.

Displaying System Logs

This topic describes how to display local system logs.

Displaying Events Logs

The Events logs include system events, such as session timeouts, system errors and warnings, requests to check server connectivity, and system restart notifications. The local log viewer displays the most recent 5000 log messages (the display limit).

To display Events logs:

1. Select **System > Log/Monitoring**.
2. Click the **Events** tab.
3. Click the **Log** tab to display the log page.

4. Use the features described in table to examine log records or manage the log collection.

Controls	Description
Filter	<p>Select a filter format. Any custom filter formats and the following predefined filter formats are available:</p> <ul style="list-style-type: none"> Standard (default)—This log filter format logs the date, time, node, source IP address, user, realm, event ID, and message. WELF—This customized WebTrends Enhanced Log Format (WELF) filter combines the standard WELF format with information about the system realms, roles, and messages. WELF-SRC-2.0-Access Report—This filter adds access queries to the customized WELF filter. You can use this filter with NetIQ's SRC to generate reports on user access methods.

Controls	Description
	 Format filters change only the data displayed (or columns exported), and do not affect the log data that has been collected.
Query	<p>In the log display, several fields are hyperlinks. The hyperlinks function as dynamic queries on the local log collection. For example, if you click the log ID, the date, or an IP address or username, the log viewer queries the log collection for records that match the value you clicked, and redisplay the log collection. You can apply additional query filters by clicking additional hyperlinked values, essentially creating a Boolean AND query (for example, date AND IP address). Use the Reset Query button to clear the query filters and redisplay the unfiltered log collection.</p> <p>Use the Save Query button to save the dynamic log query as a custom filter. When you click the Save Query button, the system displays the Filters tab displays with the Query field prepopulated with the variables you selected from the log.</p> <hr/>  Query filters change only the display (or rows exported), and do not affect the log data that has been collected.
Save Log As	<p>Save the local log collection to a file. We recommend you retain the system generated log name, which follows a consistent convention: pulsescore.logtype.nodename.log.</p> <p>The local log viewer displays the most recent 5000 log messages (the display limit). If the current log file contains fewer than 5000 log messages, older log messages from the backup log file are displayed, up to a total of 5000 log messages. This makes the log files appear as one, even though they are stored separately.</p> <p>When you save the log messages or use the FTP archive function, the backup log file is appended to the current log file, and is then downloaded as one log file. If the log files are not archived or saved by the time they are rolled over again, the oldest log messages (saved in the backup log file) are lost.</p>
Clear Log	<p>Clear the local log and log.old file.</p> <p>When you clear the local log, events recorded by the syslog server are not affected. Subsequent events are recorded in a new local log file.</p>

Controls	Description
Save All Logs	The Save All Logs button appears on the Events, User Access, and Admin Access tabs. When you click Save All Logs , the system generates a file that includes event, user access, admin access, and XML data for all of the system statistics and graphs shown on the Status > Overview page. After you click Save All Logs , you are prompted to download a file named pulsesecurelogs-graphs.tar.gz to your local host.
Clear All Logs	The Clear All Logs button appears on the Events, User Access, and Admin Access tabs. It clears event, user access, admin access, and XML data for all of the system statistics and graphs shown on the Status > Overview page. When you clear the local log, events recorded by the syslog server are not affected. Subsequent events are recorded in a new local log file.

Displaying User Access Logs

The User Access logs include information about user access, such as the number of simultaneous users at each one hour interval (logged on the hour) and user sign-ins and sign-outs. The local log viewer displays the most recent 5000 log messages (the display limit).

To display User Access logs:

1. Select **System > Log/Monitoring**.
2. Click the **User Access** tab.
3. Click the **Log** tab.

Displaying Admin Access Logs

The Admin Access logs include information about administrator actions, such as administrator changes to user, system, and network settings. It includes a log entry whenever an administrator signs in, signs out, or changes licenses on the appliance. The local log viewer displays the most recent 5000 log messages (the display limit).

To display Admin Access logs:

1. Select **System > Log/Monitoring**.
2. Click the **Admin Access** tab.

3. Click the **Log** tab.
4. Use the features to examine log records or manage the log collection.

Configuring Log Events Settings

The log type has its own settings that allow you to specify which events are logged, the maximum file size, and whether to log events to system log server in addition to logging them locally.

To configure log event categories:

1. Select **System > Log/Monitoring**.
2. Click the **Settings** tab to display the configuration page.
3. Complete the configuration as described below.
4. Save the configuration.

Syslog Servers

Events are logged locally. You can also log them to one or more external Syslog servers.
Please make sure the server(s) are reachable via port(s) configured here and at Advanced Networking page.
If Global option is chosen then interface will be taken from Advanced Networking page Syslog Settings.

Delete

Server name/IP	Facility	Type	Client Certificate	Filter	Source Interface	
	LOCAL0	UDP	Select Client Cert	Standard: Standard (default)	Global	Add

i

To configure log events for each local log category, you must perform this procedure on each local log tab: Events, User Access, and Admin Access.

Settings	Guidelines
Maximum Log Size	
Max Log Size	Specify the maximum size of the local log. The default is 200 MB. The maximum is 500 MB. The default is a good choice for logs formatted with the Standard format. If you use a more verbose format, such as WELF, specify a larger value.

Settings	Guidelines
	<p>When the local log reaches the maximum log size, the current data is rolled over to a backup log file. A new, empty, file is then created for all subsequent (new) log messages. The log viewer displays the most recent 5000 log messages (the display limit). If the current log file contains fewer than 5000 log messages, older log messages from the backup log file can be displayed, up to a total of 5000 log messages. This makes the log files appear as one, even though they are stored separately.</p> <p>When you save the log messages or use the FTP archive function, the backup log file is appended to the current log file and is then downloaded as one log file. If the log files are not archived or saved by the time they are rolled over again, the oldest log messages (saved in the backup log file) are lost.</p>
Archiving	Click the Archiving link to display the configuration page for Archiving jobs, including log archiving.
Select Events to Log – Events Tab	
Connection Requests	Log events related to connection requests.
System Status	Log events related to changes in system status.
System Errors	Log events related to system errors.
Enforcer Events	Log events related to Infranet Enforcer communication.
Enforcer Command Trace	Log events related to Infranet Enforcer command execution.
Statistics	Log user access statistics reported on the System > Log/Monitoring > Statistics tab. If you unselect the Statistics option, the statistics are not written to the log file, but are still reported on the statistics page.
Performance	Log events related to performance, such as CPU utilization.
License Protocol Events	Log events related to licensing.
RADIUS Statistics	Logs events related to RADIUS.

Settings	Guidelines
Select Events to Log – User Access Tab	
Login/log out	Log events related to sign in and sign out.
User Settings	Log events related to changes to user settings.
Client Certificate	Log events related to certificate security.
Enforcer Deny Messages	Log events related to Infranet Enforcer.
RADIUS Accounting Messages	Log events related to RADIUS.
Endpoint Heartbeat Messages	Log events related to endpoint heartbeat messages.
Ivanti Secure Access Client Messages	Log events related to Ivanti Secure Access Client.
Select Events to Log – Admin Access Tab	
Administrator changes	Log events related to configuration changes.
Administrator log ins	Log events related to administrator access.
License changes	Log events related to licensing.

Log Filtering

Ivanti Policy Secure(IPS) allows you to filter and format the data in your events, user access, and administrator access log files. When you filter log files, IPS displays only those messages specified within the filter query. For example, you can create a query that logs only entries for a particular range of IP addresses, or users who are signed into a specific realm. This topic describes how to use log filters.

Creating a Custom Log Collection Filter

If desired, you can create custom log collection filters to change the records displayed or exported. For example, it is common to see administrators use a filter for RADIUS accounting logs. This filter allows only the accounting log message, and it puts the entire message in a comma separated list. The order of the filtered message is: Date, Time, User, Realm, "List of Roles", NAS-ID, Acct-Status, Auth-Type, Attr-Value1, Attr-Value2, Attr-Value3.

Accounting attribute messages are different from authentication attribute messages in that the attribute name is not printed in the log message, but a comma is inserted for every attribute to be logged, even if it is not present.

To create a custom log collection filter:

1. Select **System > Log/Monitoring**.
2. Click the **Events** tab.
3. Click the **Filter** tab.
4. Click **New Filter** to display the configuration page.
5. Complete the configuration as described in table.
6. Save the configuration.

Settings	Guidelines
Filter Name	Specify a name that is helpful to you and other administrators in understanding usage for your customer filter.
Make default	Make the filter the default on syslog and archiving configuration pages.
Query	
Start Date	Enter a start date. Click Earliest Date to write all logs from the first available date stored in the log file.
End Date	Enter an end date. Click Latest Date to write all logs up to the last available date stored in the log file.
Query	Use the Filter Variables Dictionary to insert query expressions in the Query box. Enclose the query value in single quotes.

Settings	Guidelines
	For example, insert the query expression sourceip= . Then complete the expression by adding the value '192.168.0.1' .
Export Format	<p>Select an export format:</p> <ul style="list-style-type: none"> • Standard (default)—This log filter format logs the date, time, node, source IP address, user, realm, event ID, and message. • WELF—This customized WebTrends Enhanced Log Format (WELF) filter combines the standard WELF format with information about the system realms, roles, and messages. • Custom—Use the Standard as a template for your custom selection of columns to be included in exports (when log collections are saved to files).

Log query filters change only the data displayed (or rows exported). Log format filters change only the data displayed (or columns exported). Use of filters does not affect the log data that has been collected.

Reviewing the Configuration of Predefined Log Format Filters

To view the configuration of predefined log format filters:

1. Select **System > Log/Monitoring**.
2. Click the **Events** tab.
3. Click the **Filter** tab to display the log filters page.
4. Click the hyperlinked name of the filter to display its configuration page. You cannot edit the predefined filter named Standard, but you may edit the predefined WELF filters and any other custom filters that appear in the list.

Example: Using the Source IP Address Filter

When drilling into logs to verify behavior or troubleshoot an issue with a dual-stack device, it is helpful to redisplay the log collection filtered on the IP address.

To filter on an IP address:

1. Select **System > Log/Monitoring**.
2. Create the filter:
3. Select **User Access** and then **Filter**.
4. Define the filter expression, name the filter, and click **Save**. In this example, we create a filter based on source IP address and name it **IPv6_Address_Filter:Standard**.
5. Use the filter:
6. Select **Logs** to display the user logs table.
7. Under View by filter, select **IPv6_Address_Filter:Standard**.
8. If desired, under Edit Query, edit the value of the **sourceip= variable expression to filter on different source IP** addresses.
9. Click **Update** to apply the filter and redisplay the log collection.

Displaying User Access Statistics

Every hour, the system logs the peak count of Web users in the previous hour. It displays the hourly counts for the past week on the Statistics page. It writes the report to the system log once a week.

To display user statistics:

1. In the admin console, select **System > Log/Monitoring**.
2. Click the **Statistics** tab to display the page.
3. Scroll the page to view the data.

Upgrading software clears all statistics. If you configure the system to log statistics hourly, however, older statistics are still available in the log file after an upgrade.

Monitoring using SNMP

You can use a third-party SNMP manager, such as HP OpenView, to monitor IPS system health. IPS supports SNMP version 2 (v2) and SNMPv3. IPS implements a private MIB, and defines its own traps. Download the IPS MIB file and specify the appropriate information to receive the traps.

To configure the SNMP agent:

1. Select **System > Log/Monitoring**.
2. Click the **SNMP** tab to display the SNMP configuration page.
3. Complete the configuration as described in table.
4. Save the configuration.

Keep the following configuration tips in mind when you configure your SNMP manager to listen for this SNMP agent:

Settings	Guidelines
MIB File	Use the Ivanti MIB file link to download the device management information base MIB file. You add this file to your SNMP manager configuration.
SNMP Version	Select your SNMP server version: v2c v3
Agent Properties	
SNMP Queries	Select to support SNMP queries.
SNMP Traps	Select to send SNMP traps.
System Name	Specify a system name.
System Location	Specify a location.
System Contact	Specify a system contact.
Community String	<ul style="list-style-type: none">· Required only for SNMPv2c.· To query the system, your network management station must send it the community string.· To stop the SNMP system, clear the community field.
SNMPv3 Configuration	

Settings	Guidelines				
Username	Specify the SNMPv3 username. The User-Based Security Model (USM) is the default Security Module for SNMPv3. The system supports only one user at a time to be registered with an SNMP engine. Editing the SNMPv3 user attributes overwrite any already registered SNMPv3 user. The SNMPv3 user must have read-only access on all MIBs supported by the system. SNMPv3 user configuration attributes can also be used for SNMP traps.				
Security Level	Selection	Auth Protocol	Auth Password	Priv Protocol	Priv Password
	No Auth, NoPriv	—	—	—	—
	Auth, NoPriv	Select MD5 (HMAC-MD5-96) or SHA (HMAC-SHA-96).	Enter an authentication password. The password can contain any ASCII characters and must be at least 8 characters in length.	—	—
	Auth, Priv	Select MD5 (HMAC-MD5-96) or SHA (HMAC-SHA-96).	Enter an authentication password. The password can contain any ASCII characters and must be at least 8 characters in length.	Select either CBC-DES or CFB-AES-128.	Enter a privacy password. The password can contain any ASCII characters and must be at least 8 characters in length.
Trap Thresholds	 Setting a threshold value to 0 disables that respective trap.				

Settings	Guidelines
Check Frequency	Specify the frequency in seconds for sending traps. The default is 180 seconds.
Log Capacity	Specify the percent of log space used. The default is 90%.
Users	Specify the percent of user capacity used. The default is 100%.
Physical Memory	Specify the percent of physical memory used. The default is 0 (not reported).
Swap Memory (Virtual Memory)	<p>Specify the percent of swap memory used. The default is 0 (not reported).</p> <div>  <p>We recommend you monitor swap memory to alert you to potential memory issues. The threshold for traps for physical memory usage might be reached even if the system is not experiencing any difficulties.</p> </div>
Disk	Specify the percent of disk utilization. The default is 80%.
CPU	Specify the percent of CPU utilization. The default is 0 (not reported).
Meeting Users	Specify the percent of meeting users. The default is 100%.
Optional Traps	
Critical Log Events	Send traps when the system logs critical events.
Major Log Events	Send traps when the system logs major events.
Save SNMP Settings?	Click Save Changes to update the SNMP agent configuration. The page is refreshed and displays the SNMP engine ID. If the configuration is changed to move from SNMP v2c to SNMP v3, the system generates and displays two engine IDs.
SNMP Servers	
Hostname / IP address	Specify the hostname or IP address for the SNMP servers to which the system will send any traps it generates.
Port	Specify the port for the SNMP server. Typically, SNMP uses port 162.
Community	Specify the community string (if necessary).

- Add the Ivanti MIB file to the SNMP manager configuration.
- If using SNMPv2c, the community string configuration for the SNMP manager and SNMP agent must match.
- If using SNMPv3, the SNMPv3 user configuration for the SNMP manager and the SNMP agent must match.
- If using SNMPv3, you must specify the Authoritative Engine ID for SNMPv3 traps that was generated when you saved the SNMP agent configuration.

The table below is a reference of MIB objects for the system.

Object	Description
logFullPercent	Returns the percentage of available file size filled by the current log as a parameter of the logNearlyFull trap.
signedInWebUsers	Returns the number of users signed in through a Web browser.
signedInMailUsers	Returns the number of users signed in to the e-mail client.
blockedIP	Returns the IP address—blocked due to consecutive failed log in attempts—sent by the iveTooManyFailedLoginAttempts trap. The system adds the blocked IP address to the blockedIPList table.
authServerName	Returns the name of an external authentication server sent by the externalAuthServerUnreachable trap.
productName	Returns the licensed product name.
productVersion	Returns the software version.
fileName	Returns the file name sent by the archiveFileTransferFailed trap.
meetingUserCount	Returns the number of concurrent meeting users sent by the meetingUserLimit trap.

Object	Description
iveCpuUtil	Returns the percentage of CPU used during the interval between two SNMP polls. This value is calculated by dividing the amount of CPU used by the amount of CPU available during the current and previous SNMP polls. If no previous poll is available, the calculation is based on the interval between the current poll and system boot.
iveMemoryUtil	Returns the percentage of memory utilized by the system at the time of an SNMP poll. The system calculates this value by dividing the number of used memory pages by the number of available memory pages.
iveConcurrentUsers	Returns the total number of users logged in.
clusterConcurrentUsers	Returns the total number of users logged in for the cluster.
iveTotalHits	Returns the total number of hits to the system since last reboot. Includes total values from iveFileHits, iveAppletHits, meetingHits, and iveWebHits.
iveFileHits	Returns the total number of file hits to the system since last reboot. Incremented by the Web server with each GET/POST corresponding to a file browser request.
iveWebHits	Returns the total number of hits by means of the Web interface since last reboot. Incremented by the Web server for each http request received by the system, excluding file hits, applet hits, and meeting hits.
iveAppletHits	Returns the total number of applet hits to the system since last reboot. Incremented by the Web server for each GET request for a Java applet.
ivetermHits	Returns the total number of terminal hits to the system since last reboot.

Object	Description
logName	Returns the name of the log (admin/user/event) for the logNearlyFull and iveLogFull traps.
iveSwapUtil	Returns the percentage of swap memory pages used by the system at the time of an SNMP poll. The system calculates this value by dividing the number of swap memory pages used, by the number of available swap memory pages.
diskFullPercent	Returns the percentage of disk space used in the system for the iveDiskNearlyFull trap. The system calculates this value by dividing the number of used disk space blocks by the number of total disk space blocks.
blockedIPList	Returns a table with the 10 most recently blocked IP addresses. The blockedIP MIB adds blocked IP addresses to this table
ipEntry	An entry in the blockedListIP table containing a blocked IP address and its index (see IPEntry).
IPEntry	The index (ipIndex) and IP address (ipValue) for an entry in the blockedIPList table.
ipIndex	Returns the index for the blockedIPList table.
ipValue	A blocked IP address entry in the blockedIPList table.
logID	Returns the unique ID of the log message sent by the logMessageTrap trap.
logType	Returns a string sent by the logMessageTrap trap stating whether a log message is major or critical.
logDescription	Returns a string sent by the logMessageTrap trap stating whether a log message is major or critical.
Name	Returns the name of a virtual system.
ocspResponderURL	Returns the name of an OCSP responder.

Object	Description
fanDescription	Returns the status of the system fans.
psDescription	Returns the status of the system power supplies.
raidDescription	Returns the status of the system RAID device.
iveLogNearlyFull	<p>The log file (system, user access, or administrator access) specified by the logName parameter is nearly full. When this trap is sent, the logFullPercent (%of log file full) parameter is also sent. You can configure this trap to be sent at any percentage. To disable this trap, set the Log Capacity trap threshold to 0%. The trap's default value is 90%.</p> <p>When SNMP traps are enabled, the iveLogNearlyFull and iveLogFull traps are sent when the log files are 90% full and 100% full respectively, even if the threshold is set to 0 (disabled).</p>
iveLogFull	<p>The log file (system, user access, or administrator access) specified by the logName parameter is completely full.</p> <p>NOTE: When SNMP traps are enabled, the iveLogNearlyFull and iveLogFull traps are sent when the log files are 90% full and 100% full respectively, even if the threshold is set to 0 (disabled).</p>
iveMaxConcurrentUsersSignedIn	Maximum number or allowed concurrent users are currently signed in. You can configure this trap to be sent at any percentage. To disable this trap, set the Users trap threshold to 0%. The trap's default value is 100%.
iveTooManyFailedLoginAttempts	A user with a specific IP address has too many failed sign-in attempts. Triggered when a user fails to authenticate according to the settings for the Lockout options on the Security Options tab.

Object	Description
	When the system triggers this trap, the system also triggers the blockedIP (source IP of log in attempts) parameter.
externalAuthServerUnreachable	An external authentication server is not responding to authentication requests. When the system sends this trap, it also sends the authServerName (name of unreachable server) parameter.
iveStart	The system has just been turned on.
iveShutdown	The system has just been shut down.
iveReboot	The system has just been rebooted.
archiveServerUnreachable	The system is unable to reach the configured archive server.
archiveServerLoginFailed	The system is unable to log into the configured archive server.
archiveFileTransferFailed	The system is unable to successfully transfer files to the configured archive server. When the system sends this trap, it also sends the fileName parameter.
iveRestart	Supplies notification that the system has restarted according to the administrator's instruction.
iveDiskNearlyFull	Supplies notification that the system disk drive is nearly full. When the system sends this trap, it also sends the diskFullPercent parameter. You can configure this trap to be sent at any percentage. To disable this trap, set the Disk trap threshold to 0%. This trap's default value is 80%.
iveDiskFull	Supplies notification that the system disk drive is full.

Object	Description
logMessageTrap	The trap generated from a log message. When the system sends this trap, it also sends the logID, logType, and logDescription parameters.
memUtilNotify	Supplies notification that the system has met the configured threshold for memory utilization. To disable this trap, set the Physical Memory trap threshold to 0. The threshold is 0%, by default.
cpuUtilNotify	Supplies notification that the system has met the configured threshold for CPU utilization. To disable this trap, set the CPU trap threshold to 0. The threshold is 0%, by default.
swapUtilNotify	Supplies notification that the system has met the configured threshold for swap file memory utilization. To disable this trap, set the Swap Memory trap threshold to 0. The threshold is 0%, by default.
iveFanNotify	Supplies notification that the status of the fans has changed.
ivePowerSupplyNotify	Supplies notification that the status of the power supplies has changed.
iveRaidNotify	Supplies notification that the status of the RAID device has changed.
iveNetExternalInterfaceDownTrap (nicEvent)	Supplies the type of event that brought down the external interface. The nicEvent parameter can contain values of "external" for an external event and "admin" for an administrative action.
iveNetInternalInterfaceDownTrap (nicEvent)	Supplies the type of event that brought down the internal interface. The nicEvent parameter can contain values of "external" for an external event and "admin" for an administrative action.

Object	Description
iveClusterDisableNodeTrap (clusterName,nodeList)	Supplies the name of the cluster that contains disabled nodes, as well as a string containing the names of all disabled nodes. Node names are separated by white space in the string.
iveClusterChangedVIPTrap(vipType, currentVIP, newVIP)	Supplies the status of a virtual IP for the cluster. The vipType indicates whether the changed VIP was external or internal. The currentVIP contains the VIP prior to the change, and newVIP contains the VIP after the change.
iveNetManagementInterfaceDownTrap (nicEvent)	Supplies the type of event that brought down the management port. The nicEvent parameter can contain values of "external" for an external event and "admin" for an administrative action.
iveClusterDelete(nodeName)	Supplies the name of the node on which the cluster delete event was initiated.
pclsRemainingGracePeriod	Number of days remaining in grace period for contacting PCLS
iveMaxConcurrentUsersLicenseCapacity	Total licensed concurrent users capacity

Configuring an External Syslog Server

Ivanti Policy Secure(IPS) allows you to send the log data to an external syslog server. You should use syslog if your enterprise has any long-term record-keeping or accounting requirements.

To configure reporting to a syslog server:

1. Select **System > Log/Monitoring**.
2. Click the **Settings** tab.
3. Specify the maximum log size and select the events to be logged.
4. Specify the server configuration as described below and click Add. You can specify multiple

syslog servers.

5. Save the configuration.

To enable syslog reporting for each local log category, you must perform this procedure on each local log tab: Events, User Access, and Admin Access.

Settings	Guidelines
Server name/IP	Specify the fully qualified domain name or IPv4/IPv6 address for the syslog server. NOTE: If you select TLS from the Type list, the server name must match the CN in the subjectDN in the certificate obtained from the server.
Facility	Select a syslog server facility level (LOCAL0-LOCAL7). Your syslog server must accept messages with the following settings: facility = LOG_USER and level = LOG_INFO.
Type	Select the connection type to the syslog server. You can select: <ul style="list-style-type: none"> • UDP (User Datagram Protocol) - A simple non-secure transport model. • TCP (Transmission Control Protocol) - A core protocol of the Internet Protocol suite (IP), but lacks strong security. • TLS (Transport Layer Security) - Uses cryptographic protocols to provide a secure communication.
Client Certificate	(optional) If you select TLS from the Type menu and your remote syslog server requires client certificates, select the installed client certificate to use to authenticate to the syslog server. Client certificates are defined in the Configuration > Certificates > Client Auth Certificates page. Client certificates must be installed on the device before they can be used. <div> There is no fallback if a connection type fails. </div>
Filter	Select a filter format. Any custom filter format and the following predefined filter formats are available: <ul style="list-style-type: none"> • Standard (default)—This log filter format logs the date, time, node, source IP address, user, realm, event ID, and message.

Settings	Guidelines
	<ul style="list-style-type: none">• WELF—This customized WebTrends Enhanced Log Format (WELF) filter combines the standard WELF format with information about the system realms, roles, and messages.• WELF-SRC-2.0-Access Report—This filter adds access queries to the customized WELF filter. You can use this filter with NetIQ's SRC to generate reports on user access methods.

Configuring Advanced Settings

This option helps to configure fault tolerance on each configured TCP and TLS syslog server available. Fault tolerance is supported only for TCP and TLS syslog servers. UDP syslog servers cannot be configured for fault-tolerance. This functionality helps the syslog server to recover the logs lost during a disconnect. The administrator can configure fault-tolerance on syslog servers by enabling this option from the admin UI. IPS/ICS reads the lost pending logs during a disconnect from the log disk and transports them to the syslog server on a reconnect. Fault tolerance is supported only for the syslog servers configured under the following log-types:

- Events
- User Access
- Admin Access

Fault tolerance is node-specific. In case of clusters, the setting needs to be enabled/disabled by logging into each of the cluster members.

To configure advance settings to a TCP and TLS syslog server:

1. Select **System > Log/Monitoring**.
2. Click the **Advance Settings** tab to display the configuration page.
3. Complete the configuration as described in table.
4. Save the configuration.

This feature is limited to configuring fault tolerance settings of an existing syslog server; and cannot be used to create or delete a new syslog server.

Settings	Guidelines
Syslog Server Fault Tolerance	
Syslog Server	Lists the existing Syslog servers.
Type	Specifies if the Syslog server is a TLS or TCP type.
Fault Tolerance	Tolerates the loss of network connection to a TCP/TLS syslog server for a brief period (maximum of 4 hours) by sending the logs missed during the disconnect time. Click the checkbox to enable this option. Fault-tolerance is disabled by default on any syslog server.

Enabling Client-Side Logging

Client-side logging is not enabled by default. You can enable client-side logging for Host Checker. IPS writes a client side log to endpoints when client side logging is enabled.

To enable client-side logging:

1. Select **System > Log/Monitoring**.
2. Click the **Client Logs** tab to display the configuration page.
3. Select the **Host Checker** option to enable client-side logging when Host Checker is run on the endpoint.
4. Save the configuration.

Displaying System Status

The System Status page is a dashboard of system version information, system capacity utilization, uptime, and summary user information. The System Status page is the “home” page that is displayed when you log into the admin console as an administrator.

To navigate to the System Status page from other admin console pages, select System > Status,

The table that follows describes the various options available.

Item	Description
1	Click the Critical Events link to display a new window with a table of the last 10 critical system events.
2	Click the Page Settings link to display a new window with the System Status Settings page.
3	Click the System Version Download Package link to download the software version running on the system. You might do this when you need to synchronize software on another node to the software version running on this system.
4	Click the System Date and Time Edit link to display the System Date and Time configuration page.
5	Click a System Capacity Utilization report Edit link to display a new window with controls to customize the appearance of the report graphs.
6	Click a System Capacity Utilization report Download link to download graph data in XML format.
7	Click an Enforcer Status link to navigate to its configuration page.

Item	Description
Licenses	
Max Licensed Users	Displays the maximum number of licensed users by supported platform type.
User Licenses Consumed	Displays how user licenses are being used. Ivanti Secure Access Client connections and agentless connections count as user licenses.
Total Users	
User Licenses	Displays the number of Ivanti Secure Access Client connections and agentless connections. These types of connections count as user licenses. The maximum number of licenses is the sum of the capacity provisioned by the licenses that have been added to the system.

Item	Description
MAC Address Users	Displays the number of connections through MAC Address authentication realms. This number is reported only if a MAC Address realm has been configured. These connections do not count as user licenses, and there is no maximum number of licenses set by rule.
RADIUS Users	Displays the number of RADIUS user connections. These connections do not count as user licenses, and there is no maximum number of licenses set by rule.
Total Signed-In Users	Displays the sum of user licenses in use. <ul style="list-style-type: none">· User Licenses count· MAC Address Users count· RADIUS Users count

You can use this page to select the reports displayed on the System Status page, as well as data properties, such as the time dimension and refresh rate.

The following reports are available:

- **Concurrent Users**—Shows a count of users signed into the system. In clustered environments, the graph includes two lines. The first line displays the number of local users signed into the node selected from the list, and the second line displays the number of concurrent users signed into the entire cluster.
- **Hits per Second**—Shows a count of hits currently being processed by the system. In a clustered environment, you may select a node from the list to determine which node's data is displayed in the graph. The graph includes three lines: total number of hits, number of Web hits, and number of client/server hits.
- **CPU and Memory Usage**—Shows the percentage of the CPU and memory being used. In a clustered environment, you may select a node from the list to determine which node's data is displayed in the graph.
- **Throughput**—Shows the amount of data (in KB) being processed. In a clustered environment, you may select a node from the list to determine which node's data is displayed in the graph. The graph includes four lines: external in, external out, internal in, and internal out.
- **Connections**—Shows a count of concurrent SSL connections.
- **Rates**—Shows the rate of attempted log ins, successful log ins, and Host Checker updates.

Displaying Hardware Status

You can use the Maintenance > System > Platform page to display the hardware health status, including information about hard drives, fans, and power supplies.

To display hardware health status:

1. Select **Maintenance > System > Platform** to display the System Maintenance page.
2. Review the hardware status information described in table.

The below table lists the RAID status and hard drive status. Depending on your system, you may or may not see all these possible statuses.

Hardware Component	Status Message
Hard Disk Status	Displays a health statement for the device disk drive.
Fan Status	Displays a health statement for the device fan(s).
Power Supply	Displays a health statement for the device power supply.

RAID Status	Drive 1	Drive 2
Hard Disk RAID is operational	Active	Active
Hard Disk RAID is in single drive mode	Missing	Active
Hard Disk RAID is in single drive mode	Active	Missing
Hard Disk RAID has failed	Failed	Active
Hard Disk RAID has failed	Active	Failed
Hard Disk RAID is in the process of recovering	Active	Reconstructing
Hard Disk RAID is in the process of recovering	Reconstructing	Active
Hard Disk RAID is in the process of recovering	Active	Verifying
Hard Disk RAID is in the process of recovering	Verifying	Active

RAID Status	Drive 1	Drive 2
Hard Disk RAID status is unknown	Unknown	Active
Hard Disk RAID status is unknown	Active	Unknown
Hard Disk RAID status is unknown	Unknown	Unknown
Not available	n/a	n/a

LCD Display

This section describes the addition of LCD to IPS devices.

Overview of adding LCD for IPS

The addition of a LCD screen allows field technicians to quickly gauge the health of the system without logging into the device. The buttons on the LCD panel allow navigation through the display menus. The directional buttons are used to access the menu modes and find device information. The LCD can display two line of text. The below figure shows the LCD screen with navigation buttons.

Modes Supported by the LCD

The LCD supports two modes namely the display mode (default) and the menu mode. Pressing any button in the display mode will change the mode to menu mode. If a user presses the cancel button, the LCD immediately changes back to display mode and shows the appropriate state. The LCD remains in display mode. If the LCD is in menu mode and the user does not press any button for more than two minutes, then the LCD changes back to display mode. The below figure shows the two modes supported by the LCD

Display Mode

The display mode describes the current state of the system, such as normal state or error conditions (e.g., fan speed and overheat). It represents the default status. The LCD goes into display mode after boot-up is complete. In display mode, the LCD is either set to NORMAL or shows a label that describes an error condition. If all systems are functioning normally, then the LCD shows NORMAL. The second line in the NORMAL state is used to show whether the appliance is configured as part of a cluster. The valid states in the display mode are Clustering OFF and Clustering ON.

Detecting Error Conditions in Display Mode

If more than one error condition is detected, all error conditions will be displayed in sequence with a 2 second pause before switching to the next one. All error conditions need to be cleared before the status returns back to the NORMAL state. Error conditions include:

- Overheat
- Fan Failure
- RAID Errors

If there are any error conditions, they are automatically shown on the LCD screen when it is in the display mode. The types of errors displayed are: Fan Failures, CPU overheating and RAID errors. If there are multiple errors they would be displayed in the order with a two second pause between successive displays.

The error message is automatically cleared when the underlying error condition is resolved. For example: the CPU overheat message disappears when CPU temperature is lowered. The user can enter the Menu mode at any point, even if an error message is being displayed.

Menu Mode

The menu mode is activated when the user presses any button. A single press of the button changes to menu mode and loads the last selected menu selection.

To view information in the menu mode:

1. Press any button. This puts the LCD into menu mode.
2. Press the right and left arrows keys to obtain the available system configuration data.
3. View information starting with the Internal IP and moving in a clockwise direction.
4. The menu screens loop back in a cycle.
5. Press Cancel at any point to exit to display mode.

Any button, even cancel will put the user in the menu mode.

Displaying Active Users

You can use the Active Users page to display the system active users table and to perform administrative actions pertaining to active sessions.

The system active users table displays all users who have an active session (in contrast to the users tables that appear on the authentication server configuration pages, which display session records for active and inactive sessions that were authenticated by the particular authentication server).

If a user signs in and is placed in a VLAN without an IP address, the table does not display an IP address under Signed in IP.

If there is a NAT device between the user's computer and the Infranet Enforcer, the table displays both the NAT device's IP address and the endpoint's virtual source IP address under Signed in IP. For example, if the NAT device's IP address is 10.64.9.26, and the endpoint's virtual source IP address is 192.168.80.128, the following information is displayed under Signed in IP: 10.64.9.26 (192.168.80.128 behind NAT).

To display the system Active Users page:

1. Select **System > Status**.
2. Click the **Active Users** tab to display the system active users page.
3. Use the controls described in table below to perform administrative actions pertaining to active sessions.

Profiler publishes signed in IP address in Active users page only if RADIUS Accounting is disabled and signed in IP is not available for the user session.

Buttons	Administrative Actions
Update	<p>Refresh records displayed on the page:</p> <ul style="list-style-type: none">• To refresh the page, click Update.• To display a specific user, enter the username in the Show Users Named box and click Update. If you do not know the exact username, use the asterisks (*) as a wildcard character.• To change the table size, enter a number in the Show N users box and click Update.

Buttons	Administrative Actions
	 To sort the table of currently signed-in users and administrators, click a column header.
Delete Session	Select the check box next to the appropriate names and then click Delete Session to immediately delete the session. The user is signed out by your action.
Delete All Sessions	<p>Use this option to immediately delete all sessions. Users are signed out by your action.</p>  If you want to sign out administrators, you must choose them individually and use the Delete Session button.
Refresh Roles	Manually evaluate all authentication policies, role-mapping rules, role restrictions, user roles, and resource policies for all currently signed-in users. Use this button if you make changes to an authentication policy, role-mapping rules, role restrictions, or resource policies and you want to immediately refresh the roles of all users.
Disable All Users	Sign out all end users who are currently signed-in and also prevent any other users from signing in. To allow users to sign in again after you disable all users, click Enable All Users.

Troubleshooting

Overview

You can use the admin console troubleshooting tools to investigate user access issues and system issues. The following tools are available through the Maintenance > Troubleshooting pages:

- Policy tracing—Diagnose user access issues.
- Debug logs—Work with PSGSC to diagnose system issues.
- RADIUS diagnostic log—Diagnose issues with IPS RADIUS server.
- tcpdump—Sniff packet headers to diagnose networking issues.
- Network troubleshooting commands—Use standard network commands, such as ping, traceroute, NSlookup, and other commands to diagnose networking issues.
- Kerberos debugging—Diagnose issues with Kerberos communication.
- System snapshots—Work with PSGSC to reproduce and diagnose system issues.
- Remote debugging—Enable PSGSC to access your system directly to help you diagnose system issues.

If the admin console is unavailable, you can use the serial port console to perform some troubleshooting operations, such as use ping and traceroute commands, view logs, create system snapshots, and perform configuration rollbacks and factory resets.

Troubleshooting

Overview

You can use the admin console troubleshooting tools to investigate user access issues and system issues. The following tools are available through the Maintenance > Troubleshooting pages:

- Policy tracing—Diagnose user access issues.
- Debug logs—Work with PSGSC to diagnose system issues.
- RADIUS diagnostic log—Diagnose issues with IPS RADIUS server.
- tcpdump—Sniff packet headers to diagnose networking issues.
- Network troubleshooting commands—Use standard network commands, such as ping, traceroute, NSlookup, and other commands to diagnose networking issues.
- Kerberos debugging—Diagnose issues with Kerberos communication.
- System snapshots—Work with PSGSC to reproduce and diagnose system issues.
- Remote debugging—Enable PSGSC to access your system directly to help you diagnose system issues.

If the admin console is unavailable, you can use the serial port console to perform some troubleshooting operations, such as use ping and traceroute commands, view logs, create system snapshots, and perform configuration rollbacks and factory resets.

Policy Tracing

It is common to encounter a situation where the system denies a user access to the network or to resources, and the user logs a trouble ticket. You can use the policy tracing utility and log to determine whether the system is working as expected and properly restricting access, or whether the user configuration or policy configuration needs to be updated to enable access in the user's case.

To create a policy trace log:

1. Select **Maintenance > Troubleshooting > Policy Tracing** to display the configuration page.

4. Initiate the action you want to trace, such as a user sign in.

5. Click **View Log** to display the policy trace results log.

6. Click **Stop Recording** when you have enough information.

Table describes options for managing the policy trace results log file.

Control	Guidelines
Delete Trace	Under Events to Log, click Delete Trace to clear the results displayed on this page.

Control	Guidelines
Update	Specify a number of rows to display and click Update to change the number of rows that are displayed.
Save Log As	Click this button to save the trace results log to a file. This is useful particularly when you are working with the Ivanti Global Support Center to troubleshoot a case.
Clear Log	Click this button to clear the log file from the system.

Debug Logs

The Ivanti Global Support Center might direct you to create a debug log to assist them in helping you debug an issue with the system. The debug log is used only by PSGSC.

To use debug logging:

1. Select **Maintenance > Troubleshooting > Debug Log** to display the configuration page.
2. Complete the configuration as described below.
3. Click **Save Changes**. When you save changes with Debug Logging On selected, the system begins generating debug log entries.
4. Initiate the action you want to debug, such as a user sign in. You can reset the debug log file to restart debug logging if it takes you too long to initiate the action.
5. Click **Save Debug Log** to save the debug log to a file that you can send to PSGSC. You can clear the log after you have saved it to a file.

- Unselect **Debug Logging On** and click **Save Changes** to turn off debug logging.

Event Codes	Specify the event code. Obtain this from PSGSC.

RADIUS Diagnostic Logs

The RADIUS diagnostic log utility allows you to view trace and debug-level RADIUS messages. When RADIUS diagnostic logging is enabled, the diagnostic tool logs all requests that IPS receives from RADIUS clients. RADIUS requests initiated by IPS do not appear in the log.

Observe the following guidelines:

- Diagnostic logging affects system performance.
- All events that appear in the log have an ID code, and all messages in a thread are tagged with the same ID. This allows you to track individual log ins or log in attempts.
- Source IP addresses are represented as 127.0.0.1 (the loopback address).
- For Layer 2 connections, the calling station ID is the MAC address of the endpoint.
- Passwords are suppressed and do not appear in the logs.
- When the log fills up, logging stops. You can clear the log to restart logging.
- Raw traffic is not available in the log. To view raw traffic, use the tcpdump feature.

To use RADIUS diagnostic logging:

1. Select **Maintenance > Troubleshooting > Diagnostics Logs** to display the configuration page.
2. Complete the configuration as described below.
3. Click Save Changes. When you save changes with RADIUS Diagnostic Logging On selected, the system begins generating diagnostic log entries.
4. Initiate the action you want to debug, such as a user sign in. You can clear the debug log file to restart diagnostic logging if it takes you too long to initiate the action.

5. Manage the resulting log:

- Click Save Log to save the log files in a zipped format.
- Click Clear Log to remove previous logs and start diagnostic logging with a fresh file.
- Click **Save And Clear Log** to save the diagnostic log to a file that you can send to PSGSC. The existing logs in the device will be cleared after saving.

6. Unselect RADIUS Diagnostic Logging On and click Save Changes to turn off diagnostic logging.

Radius Diagnostic Logging On ☐

Samba Diagnostic Logging On ☐ This option is for generating internal logs related to AD authentication server modules and the underlying Samba modules. Changing this option will restart certain modules and user logins may fail during the brief restart period.

Pulse One Diagnostic Logging On ☐ This option is for generating internal logs related to tracing information between the appliance and Pulse One Server. It should not help.

MB 1-1000

Attack Audit Logging On ☐ This option is used for to log and audit the attack record related to SYN FLOOD and SMURF. The log only captures the rest of the attack records. There are four attack types (IPv4/IPv6 SYN FLOOD, SMURF), the maximum audit log size for each type is 1000 MB.

Save Changes

Settings	Guidelines
RADIUS Diagnostic Logging On	Specify the source IP address if you know it. If you are able to provide the source IP address, the policy trace log can include events that occur before the user ID is entered into the system.

Settings	Guidelines
Max Diagnostic Log Size	Specify a maximum logfile size. The default is 1000 MB.

Samba Diagnostic Logs

The Samba diagnostic log utility allows you to view trace and debug the samba troubleshooting messages on the new AD authentication server. When samba diagnostic logging is enabled, the internal logs related to AD authentication server is generated.

Observe the following guidelines:

- Diagnostic logging affects system performance.
- Must be used only when the admin UI error messages, event logs and admin logs are not very useful.
- Enabling/Disabling samba logs will restart certain modules and user log ins may fail during the restart.
- The default debug log setting will generate minimal logs. Enabling debug log with event AAA or AAA::samba along with this feature can generate more logs based on the debug log level.

Enabling samba logs will cause logs to be generated from all configured AD authentication servers. Logs from multiple AD servers are interleaved and can be identified by the header in each line of the logs.

To use samba diagnostic logging:

1. Select **Troubleshooting > Monitoring > Diagnostic Logs** to display the configuration page.
2. Complete the configuration as described below.
3. Click Save Changes. When you save changes with Samba Diagnostic Logging On selected, the system begins generating diagnostic log entries.
4. Initiate the action you want to debug, such as a user sign in.

5. Manage the resulting log:

- Click **Save Log** to save the log files in a zipped format.
- Click **Clear Log** to remove previous logs and start diagnostic logging with a fresh file.
- Click **Save And Clear Log** to save the diagnostic log to a file that you can send to PSGSC. The existing logs in the device will be cleared after saving.

6. Unselect **Samba Diagnostic Logging On** and click **Save Changes** to turn off diagnostic logging.

TCP Dump

This is a tool to sniff the packet, when you want to examine that the expected packet really reached a node. You can run the tcpdump utility to sniff the packet headers on the network and save them on a dump file.

To use tcpdump:

1. Select **Maintenance > Troubleshooting > TCP Dump** to display the configuration page.
2. Complete the configuration as described below.
3. Click **Start Sniffing** to start the tcpdump process.
4. Initiate the action you want to debug, such as a user sign in.
5. Click **Stop Sniffing** to write the tcpdump output to the screen.

- Click **Get to save the output to a file**, or click **Delete** to clear the output.

	ip	Sniffs the IP protocol.
	tcp	Sniffs the TCP protocol.
	dst #.#.#.#	Sniffs the destination IP address specified, where #.#.#.# is a valid IP address.
	src #.#.#.#	Sniffs the source IP address specified, where #.#.#.# is a valid IP address.
	port 80 or port 443	Sniffs on port 80 or port 443.
	src #.#.#.# and dst #.#.#.#	Sniffs the source and destination IP addresses or hosts specified, where each #.#.#.# represents a valid IP address.
	tcp port 80 or port 443 and dst #.#.#.# and src #.#.#.#	This example shows how to specify multiple parameters to create a filter that sniffs on TCP port 80, or on TCP or UDP port 443, and on the destination and source ports, where each #.#.#.# represents a valid IP address.

Network Troubleshooting Commands

You can run common network troubleshooting commands such as arp, ping, ping6, traceroute, traceroute6, NSlookup, and AvgRTTs from the admin console. You can use these connectivity tools to see the network path from the system to a specified server. If a client can ping or traceroute to the access system, and the access system can ping the target server, any remote users should be able to access the server through the access system.

To run network troubleshooting commands:

1. Select **Maintenance > Troubleshooting > Commands** to display the configuration page.
2. Complete the configuration as described below.
3. Click **OK** to run the command and write the output to the screen.
4. Click **Clear** to clear the output.

Output:

None

Settings	Guidelines
Command	<p>Select a network troubleshooting command:</p> <ul style="list-style-type: none"> • Ping/Ping6-Use the ping command to verify that the system can connect to other systems on the network. In the event of a network failure between the local and remote nodes, you do not receive a reply from a pinged device. In that case, contact your LAN administrator for help. The ping command sends packets to a server and returns the server response, typically a set of statistics including the target server's IP address, the time spent sending packets and receiving the response, and other data. You can ping unicast or multicast addresses, and you must include the target server name in the request. Select ping to ping an IPv4 address or hostname. Select ping6 to ping an IPv6 address. We do not support DNS resolution for hosts with IPv6 addresses. Hence, ping6 does not support pings to hostnames. • Traceroute/Traceroute6-Use the traceroute command to discover the path that a packet takes from IPS to another host. Traceroute sends a packet to a destination server and receives an ICMP TIME_EXCEEDED response from each gateway along its path. The TIME_EXCEEDED responses and other data are recorded and displayed in the output, showing the path of the packet round-trip. Select traceroute to target an IPv4 address or hostname. Select traceroute6 to target an IPv6 address. We do not support DNS resolution for hosts with IPv6 addresses. Hence, traceroute6 does not support traceroute to hostnames. • NSLookup-Use NSlookup to get detailed information about a name server on the network. You can query on several different types of information, including a server's IP address, alias IP address, start-of-authority record, mail exchange record, user information, well-known services information, and other types of information. • ARP-Use the arp command to map IP network addresses to the hardware addresses. The Address Resolution Protocol (ARP) allows you to resolve hardware addresses. To resolve the address of a server in your network, a system sends information about its unique identifier to a server process executed on a server in the intranet. The server process then returns the required address to the client process.

Settings	Guidelines
	AvgRTTs-Use AvgRTTs to display the average round-trip time (RTT) to the localhost.
	Portprobe-Display the Transmission Control Protocol (TCP) or the User Datagram Protocol (UDP) port status (open or closed).
Target server	Specify the IP address or hostname for the target server.
Interface	Select the interface from which to send the command.
VLAN Port	Select a VLAN port, to test connectivity to a subscriber intranet.
Output	Displays command output.

Troubleshooting TCP and UDP Port Status

Problem	Description
Problem Description	The system makes several connections to back-end servers using various port numbers. If communication between the system and the back-end servers stops, it can be difficult to determine the source of the problem.
Solution	You can use the Portprobe command to display the Transmission Control Protocol (TCP) or the User Datagram Protocol (UDP) port status (open or closed).

 Only the system internal ports, management port and internal VLAN ports support the Portprobe command.

A TCP port can be closed under two conditions:

- The system sends a connection request to the back-end server port and the back-end server closes the connection (sends an RST packet).
- The connection request times out because the back-end server is not found or the back-end server is too busy to respond to the connection request.

If either of these conditions occurs, the system sends a ping command to the back-end server. If the ping command is successful, the back-end server is considered reachable but the back-end server port is closed. If the ping command fails, the back-end server is considered unreachable.

For UDP ports, the system sends a UDP datagram with a ping to the back-end server port. If the back-end server responds with Internet Control Message Protocol (ICMP) port unreachable or ICMP unreachable, the back-end port is considered unreachable. If the back-end server responds with ICMP host unreachable then the back-end server is considered unreachable.

To troubleshoot the TCP or UDP port:

1. Select **Maintenance > Troubleshooting > Tools > Commands**.
2. Select the Portprobe command.
3. Select either **TCP** or **UDP**.
4. Enter the target server and port number. You can enter an IP address, hostname or FQDN for the target server.
5. Enter the probe count. This is the number of times the system attempts to communicate with the back-end server port. The default for TCP is one; the default for UDP is five.
6. Enter the probe timeout. This is the number of seconds the system waits for a response from the back-end server port.
7. Select either the internal port or the management port. If the management port is not configured, it is not displayed.
8. If using an internal port, select the internal VLAN port from the list.
9. Click **OK**.

The following figure shows an example of a successful and an unsuccessful port probe.

Testing Server Connectivity

To run NSLookup to test name server connectivity:

1. In the admin console, choose **Maintenance > Troubleshooting > Tools > Commands**.
2. From the Command list, select **NSLookup**.
3. Select the type of query to use from the Query Type drop down menu.
4. Enter the query, which is a hostname, an IP address, or other information, depending on your selection of query type.
5. Enter the VLAN port.

- Click **OK** to run the command.

Troubleshooting > Tools > Commands

Kerberos Debugging

You can run the Kerberos debugging utility from the admin console. The utility checks the DNS infrastructure for validity of the Kerberos realms and defined credentials.

To use the Kerberos debugging utility:

- Select **Maintenance > Troubleshooting > Tools > Kerberos** to display the configuration page.
- Complete the configuration as described below.
- Click **Run** to start the debugging process.

- Click **Get to save the output to a file**, or click **Delete** to clear the output.

Remote Debugging

Remote debugging allows Ivanti Global Support Center to directly access this system over a secure connection. You should enable this feature only if you have been requested to do so by PSGSC in response to an issue that you have reported.

To enable remote debugging:

1. Select **Maintenance > Troubleshooting > Remote Debugging** to display the configuration page.
2. Complete the configuration and actions as described below.

Troubleshooting > Remote Debugging

Remote Debugging

User Sessions | Monitoring | Tools | System Snapshot | **Remote Debugging**

Remote debugging allows Pulse Secure to directly access this system over a secure connection. You should only enable this feature if you have been requested to do so by Pulse Secure Customer Support in response to an issue you have reported.

Debugging Status: Disabled

Edit log settings	To configure the settings of individual logs, click the corresponding Edit link. Complete the configuration and click Save Changes.
Stop and Save Logs	Stops the services used for the log collection and archives all the selected logs and then prompts to download the archive file.
Save Logs	Archives all the selected logs and prompts to download it as a bundle.

Troubleshooting the Common Issues with IPS

Table describes the common issues with IPS and provides the possible resolution.

Category	Description	Resolution/KB docs
Installation	Integrating Cisco IP phone 7941 or 7911G for 802.1x authentication with the IPS solution	For more information, see KB 13668 .
	Ivanti Secure Access Client prompts for certificate validation even though the Trusted Root certificate is installed	For problem resolution, see KB 23479 .
	Communication Ports that are open by default on IPS device	For more information, see KB 24280 .
Layer 2 (802.1X, MAC Auth, SNMP, RADIUS)	802.1X- "TLS handshake failed" posted to the IPS user access log	For problem resolution, see KB 13716 .
	MAC Auth- Does IPS count MAC authentication against the concurrent user license?	For more information, see KB 24574 .
	SNMP monitoring of IPS devices	For more information, see KB 26207 .
	RADIUS dropped new Radius authentication request	For resolution, see KB 30167 .
Layer 3 (SRX, SOS, PAN, Fortinet)	Delay in removal of user session from Palo Alto Firewall after termination of session on IPS	For resolution, see KB 40165 .
Host Checker		

Category	Description	Resolution/KB docs
	How to enforce domain membership with Host Checker Policy	For resolution, see KB 17389 .
Cluster	Cluster VIP flapping between both of the nodes in Active/Passive cluster	For resolution, see KB 21584 .
	Cluster Licensing Best Practices	For more information, see KB 40093 .
	<p>Do the active nodes monitor the state of their own interface? Each node monitors both of its interfaces by sending an ARP to the default gateway. This ARP message is sent every 5 seconds. The IPS waits up to 5 seconds for a response. If there is no response the IPS begins a wait period of 45 seconds. If there is still no response, the IPS marks the interface as down.</p> <hr/> <div>  <p>The ARP timeout value is configurable from the network settings page for each interface. Additionally, you can configure how many ARP ping timeouts are received before marking the interface as down. This applies to both interfaces and all nodes in the cluster. On the cluster properties page, there is an option to have each IPS disable their external interface in the event their internal interface goes down. This is a cluster-wide setting.</p> </div> <hr/>	
	<p>How big is the Synchronization Packet? This depends on how much data is synchronized. It is observed that approximately 1MB of data is transferred for 1000 users when a node is added to the cluster and synchronized. After the nodes are synchronized, data is sent only upon a status change. For example, user session status, user properties (bookmarks), or a change to the system configuration.</p>	
	<p>How does the IPS inform the local nodes if the passive becomes the Master? When one IPS fails, the other IPS detects the outage and assumes the VIP. It then issues a gratuitous ARP so that all local nodes (switches and routers included) will know the new MAC address for the VIP.</p>	
	Explanation on LEADER cluster status and Sync	For more information,

Category	Description	Resolution/KB docs
	Rank	see KB 13295 .
	I have received my replacement IPS; how do I join it to my existing cluster?	For more information, see KB 13727 .
	Procedure to collect logs	For more information, see KB 21714 .
AAA (AD, LADAP, RADIUS)	Does the IPS server support, multiple instances of Active Directory/Windows NT, for the same domain?	For resolution, see KB 21702 .
	What permissions are needed on the service account used within ICS/IPS Active Directory standard mode authentication server and how to set it up using Delegate Control Wizard	For resolution, see KB 40401 .
	Mapping based on Primary Group by using LDAP Authorization Server.	For more information, see KB 2527 .

Appendix REST API Support

Overview

The REST API provides a standardized method for Next-Gen firewalls and third-party systems to interact with IPS. **Representational state transfer (REST)** or RESTful Web services are one way of providing interoperability between computer systems on the Internet. REST-compliant Web services allow requesting systems to access and manipulate textual representations of Web resources using a uniform and predefined set of stateless operations. In a RESTful Web service, requests made to a resource's URI will elicit a response that may be in XML, HTML, JSON or some other defined format. IPS supports JSON format only.

REST methods determine the HTTP method for manipulating the resources defined in the service operation. The kind of operations available include those predefined by the HTTP verbs GET, POST, PUT, DELETE and so on. The response may confirm that some alteration has been made to the stored resource, and it may provide hypertext links to other related resources or collections of resources. By making use of a stateless protocol and standard operations, REST systems aim for fast performance, reliability, and the ability to grow, by re-using components that can be managed and updated without affecting the system as a whole, even while it is running.

REST API Support for IPS involves only Configuration APIs. IPS supports only the GET, POST, PUT and DELETE APIs.

The valid and supported values are described in table.

HTTP Verb	Definition
DELETE	Delete an existing resource.
GET	Retrieve a representation of a resource.
POST	Create a new resource
PUT	Create a new resource to a new URL, or modify an existing resource to an existing URL.

The error codes supported are described in the table.

HTTP Verb	Definition
200 OK	Requesting for resource information successful using GET Resource updation successful using PUT
201 Created	Resource creation successful using POST
204 No Content	Deletion of resource successful with no body. Even PUT, POST may return 204 if no errors or warnings seen
400 – Bad Request	Any Request (GET/PUT/POST/DELETE, and so on) is invalid. Example: Incorrect JSON format
401 – Unauthorized	Any REST Call with invalid credentials
403 – Forbidden	REST Call with valid credentials but no permission.
404 – Not found	Requested resource in URI does not exists
422 – Unprocessable Entity	Any validation/referential integrity errors that would result in failure of PUT/POST/DELETE request
500 Server Error	When IPS rest server is not responding

Authentication for REST APIs

Basic authentication using the HTTP authorization header is used to authenticate username/password on the Administrators authserver. It is expected that the user is already configured in the Administrators authserver. On a successful login, a random token (api_key) is generated and sent back as a JSON response. Further access to APIs can use this api_key in their Authorization header for access. The entire communication is over TLS. An example is explained below:

```
REQUEST
GET /api/v1/auth HTTP/1.1
Host: xx.xx.xx.xx
Authorization: Basic YWRtaW5kYjpkYW5hMTIz
Content-Type: application/json
RESPONSE
HTTP/1.1 200 OK
Cache-Control: no-store
Connection: Keep-Alive
Content-Type: application/json
```

```
Expires: -1
Keep-Alive: timeout=15
{ "api_key": "p5mMlc7RQu8lR2NvssLCCZhP05kf0N2ONFeYeLXX6aU=" }
```

Authorization header for all future request should perform Basic Auth using above api_key value as username and password as empty.

```
REQUEST
GET /api/v1/configuration HTTP/1.1
Host: xx.xx.xx.xx
Authorization: Basic
cDVtTWxjNlJRdTgxUjJOdnNzTENDWmhQMDVrZjBOMk9ORmVZZUxYWdZhVT06
RESPONSE
HTTP/1.1 200 OK
Content-Length ?283
Content-Type ?application/json
{ "
  administrators":
  { "href": "/api/v1/configuration/administrators" }
  , "
  authentication":
  { "href": "/api/v1/configuration/authentication" }
  , "
  system":
  { "href": "/api/v1/configuration/system" }
  , "
  users":
  { "href": "/api/v1/configuration/users" }
}
```

Enabling REST API Configuration

The configuration of IPS can be accessed using REST APIs. The IPS configuration is represented in a JSON form when accessed using REST APIs. The structure of the JSON representation is very similar to the structure of IPS XML configuration.

A new admin UI option for users under "Administrators" authserver has been added. REST API authentication would be successful only for those users who have this option enabled.

To enable this checkbox:

1. Go to **Authentication > Auth. Servers > Administrators > Users > New/Update**.
2. Select the **Allow access to REST APIs** checkbox.
3. Click **Save Changes**.

Sample GET/POST/PUT/DELETE Request and Responses

Below is a sample of GET/POST/PUT/DELETE request and responses:

```
REQUEST
POST /api/v1/configuration/uac/infranet-
enforcer/connections/infranet-enforcer/
HTTP/1.1

Appendix Custom Expressions and System Variables Reference

Using Custom Expressions in Rule Configuration

This topic describes custom expressions. It is intended for advanced users.

Custom Expressions

Many system rules, such as role mapping rules or resource policy rules, support custom expressions. A custom expression is a combination of variables that the system evaluates as a Boolean object. The expression returns true, false, or error.

You can write custom expressions in the following formats. Note that elements of these formats are described in greater detail in the table that follows:

- *variable comparisonOperator variable*
- *variable comparisonOperator simpleValue*
- *variable comparisonOperator (simpleValue)*
- *variable comparisonOperator (OR Values)*
- *variable comparisonOperator (AND Values)*
- *variable comparisonOperator (time TO time)*
- *variable comparisonOperator (day TO day)*
- *isEmpty (variable)*
- *isUnknown (variable)*
- *(customExpr)*
- *NOT customExpr*
- *! customExpr*
- *customExpr OR customExpr*

- *customExpr || customExpr*
- *customExpr AND customExpr*
- *customExpr && customExpr*

Custom Expression Elements

Element	
variable	<p>Represents a system variable. A variable name is a dot-separated string, and each component can contain characters from the set [a-z A-Z 0-9_] but cannot start with a digit [0-9]. Variable names are case-insensitive. For system variables that you may use in role mapping rules and resource policies.</p> <p>When writing a custom expression in a log query field, you need to use system log variables. These variables are described in the Filter Variables Dictionary on the Filter page (System > Log/Monitoring > Events User Access Admin Access > Filters > Select Filter tab).</p> <p>Quoting syntax for variables:</p> <p>The system supports a quoting syntax for custom expression variables that allows you to use any character except '.' (period) in a user attribute name. To escape characters in an attribute name, quote some or all of the variable name using { } (curly-braces). For example, these expressions are equivalent: <code>userAttr.{Login-Name} = 'xyz'</code> <code>userAttr.Login{-}Name = 'xyz'</code> <code>{userAttr.Login-Name} = 'xyz'</code> <code>userA{ttr.L}{ogin-}Name = 'xyz'</code></p> <p>Escape characters supported within quotes:</p> <ul style="list-style-type: none">• <code>\\</code> — Escape a backslash (\)• <code>\{</code> — Escape a left curly brace ({)• <code>\}</code> — Escape a right curly brace (})• <code>\hh</code> — Escape a hexadecimal value where hh is two characters from [0-9A-Fa-f] <p>Examples:</p> <p><code>userAttr.{Tree Frog} = 'kermit'</code></p> <p><code>userAttr.{Tree\20Frog} = 'kermit'</code></p>

Element	
	<div>  <ul style="list-style-type: none"> - There is no limit to the number of quotes you can use in a variable name. - You can use the quoting syntax with any variable, not just userAttr.* variables - You need to use curly-brace quotes only when writing custom expressions. </div>
<i>comparisonOperator</i>	<p>One of the following:</p> <ul style="list-style-type: none"> • = — Equal to. Use with strings, numbers, and DNs. • != — Not equal to. Use with strings, numbers, and DNs. • < — Less than. Use with numbers. • <= — Less than or equal to. Use with numbers. • > — Greater than. Use with numbers. • >= — Greater than or equal to. Use with numbers.
<i>simpleValue</i>	<p>One of the following:</p> <ul style="list-style-type: none"> • <i>string</i> — quoted string that may contain wildcards. • <i>IP Address</i> — a.b.c.d • <i>subnet</i> — a.b.c.d/subnetBitCount or a.b.c.d/netmask • <i>number</i> — Positive or negative integer • <i>day</i> — SUN MON TUE WED THU FRI SAT <p>Notes about strings: A string may contain all characters except <nl> (newline) and <cr> (carriage return). Strings can be any length. String comparisons are case-insensitive.</p>

Element	
	<p>Strings can be quoted with single- or double-quotes. A quoted string may contain wildcards, including star(*), question mark (?), and square brackets ([]).</p> <p>variable comparisonOperator variable comparisons are evaluated without wildcard matching.</p> <p>Use a backslash to escape these characters:</p> <ul style="list-style-type: none"> • single-quote (') — \' • double-quote (") — \" • backslash (\) — \\ • hexadecimal — \hh [0-9a-fA-F] <p>Note about day:</p> <p>Day and time comparisons are evaluated in the system's time zone. Day range (day TO day) calculations start with the first day and step forward until the second day is reached. In time range (time TO time) calculations, the first value must be earlier than the second value. Only time variables can be compared to day and time values. The time variables are: time.* and log inTime.*.</p>
<i>time</i>	<p>Time of day in one of the following formats:</p> <p><i>HH:MM</i> — 24-hour</p> <p><i>HH:MMam</i> — 12-hour</p> <p><i>HH:MMpm</i> — 12-hour</p> <p><i>H:MM</i> — 24-hour</p> <p><i>H:MMam</i> — 12-hour</p> <p><i>H:MMpm</i> — 12-hour</p> <p>Day and time comparisons are evaluated in the system's time zone. Day range (day TO day) calculations start with the first day and step forward until the second day is reached. In time range (time TO time) calculations, the first value must be earlier than the second value. Only time variables can be compared to day and time values. The time variables are: time.* and log inTime.*.</p>
<i>OR Value</i>	String containing one or more OR comparisons:

Element	
	<p>Examples:</p> <p><i>variable comparisonOperator (number OR number ...)</i></p> <p><i>variable comparisonOperator (string OR string ...)</i></p>
<i>AND Value</i>	<p>String containing one or more AND comparisons.</p> <p>Examples:</p> <p><i>variable comparisonOperator (number AND number ...)</i></p> <p><i>variable comparisonOperator (string AND string ...)</i></p>
<i>isEmpty</i>	<p>Function that takes a single variable name (variable) argument and returns a boolean value. isEmpty() is true if the variable is unknown or has a zero-length value, zero-length strings, and empty lists.</p> <p>Example: isEmpty(userAttr.terminationDate)</p>
<i>isUnknown</i>	<p>Function that takes a single variable name (variable) argument and returns a boolean value. isUnknown() is true if the variable is not defined. User attributes (userAttr.* variables) are unknown if the attribute is not defined in LDAP or if the attribute lookup failed (such as if the LDAP server is down).</p> <p>Example: isUnknown(userAttr.bonusProgram)</p>
<i>NOT, !</i>	<p>Logical negation comparisonOperator. The negated expression evaluates to true if the customExpr is false and evaluates to false if the customExpr is true. The operators NOT, AND, and OR are evaluated from highest to lowest precedence in this order: NOT (from right), AND (from left), OR (from left).</p>
<i>OR, </i>	<p>Logical operator OR , which are equivalent. The operators NOT, AND, and OR are evaluated from highest to lowest precedence in this order: NOT (from right), AND (from left), OR (from left).</p>
<i>AND, &&</i>	<p>Logical AND or &&, which are equivalent. The operators NOT, AND, and OR are evaluated from highest to lowest precedence in this order: NOT (from right), AND (from left), OR (from left).</p>
<i>customExpr</i>	<p>Expression written in the Custom Expression Syntax (see above).</p>

Wildcard Matching

In a quoted string, supported wildcards include:

- star (*)—A star matches any sequence of zero or more characters.
- question mark (?)—A question mark matches any single character.
- square brackets ([])—Square brackets match one character from a range of possible characters specified between the brackets. Two characters separated by a dash (-) match the two characters in the specified range and the lexically intervening characters. For example, 'dept[0-9]' matches strings "dept0", "dept1", and up to "dept9".

To escape wildcard characters, place them inside square brackets. For example, the expression 'userAttr.x = " value [*]" ' evaluates to true if attribute x is exactly "value*".

Using Multivalued Attributes

Multivalued attributes—attributes that contain two or more values—provide you with a convenient method for defining resources that expand into multiple individual bookmarks on the users' bookmarks page.

For example, assume that the user's LDAP directory contains the multivalued attribute HomeShares: \\Srv1\Sales;\\Srv2\Marketing. When you configure the Windows File share resource definition using the HomeShares multivalued attribute, \\<userAttr.HomeShares>, the user sees two bookmarks:

- \\Srv1\Sales
- \\Srv2\Marketing

Now let's assume the user's LDAP directory contains a second multivalued attribute defined as HomeFolders: Folder1;Folder2;Folder3. When you configure the Windows File share resource using both of the multivalued attributes, \\<userAttr.HomeShares>\\<userAttr.HomeFolders>, the user sees the following six bookmarks:

- \\Srv1\Sales\Folder1
- \\Srv1\Sales\Folder2
- \\Srv1\Sales\Folder3
- \\Srv2\Marketing\Folder1
- \\Srv2\Marketing\Folder2
- \\Srv2\Marketing\Folder3

The only exception to this functionality is when the variable includes an explicit separator string. In this case, only one bookmark containing multiple resources displays on the users' bookmark page.

You specify the separator string in the variable definition using the syntax `sep='string'` where string equals the separator you want to use. For example, to specify a semi-colon as the separator, use the syntax `<variable.Attr sep='; '>`.

Use the following syntax for multivalued attributes handling. Note that `<variable>` refers to a session variable such as `<userAttr.name>` or `<CertAttr.name>`:

`<variable[Index]>`—You specify indexes in a variety of ways. If, for example, the total number of values for a given index is 5, and you want to specify the entire range of values you use `<variable[ALL]>`. If you want to specify only the fourth value, you use `<variable[4]>`.

- `<variable>` is the same as `<variable[ALL]>`.
- `<variable>` is the same as `<variable[ALL]>`.
- `<variable sep='str'>` and `<variable[All] sep='str'>` — These variable definitions always refer to a single string value with all the tokens expanded out with separator strings between the values.

Variable names cannot contain spaces.

Specifying Multivalued Attributes in a Bookmark Name

Another common case of using multivalued attributes occurs when you include a variable in a bookmark name and in a URL or file server/share field.

For example, again assume that the user's LDAP directory contains the multivalued attribute HomeShares: `\\Srv1\Sales;\\Srv2\Marketing`. When you configure the Windows File share resource definition using the HomeShares multivalued attribute, `\\<userAttr.HomeShares>`, and you use the same attribute in the bookmark name field, `<userAttr.HomeShares>`, the system creates two bookmarks:

- Srv1\Sales bookmark pointing to `\\Srv1\Sales`
- Srv2\Marketing bookmark pointing to `\\Srv2\Marketing`

This does not create a situation in which you end up with the following set of conditions:

- Srv1\Sales bookmark pointing to \\Srv1\Sales
- Srv1\Marketing bookmark pointing to \\Srv1\Marketing (error)
- Srv2\Sales bookmark pointing to \\Srv1\Sales (error)
- Srv2\Marketing bookmark pointing to \\Srv2\Marketing

Distinguished Name Variables

You can compare a distinguished name (DN) to another DN or to a string, but the system ignores wildcards, white space, and case. Note, however, that the system takes the order of DN keys into consideration.

When the system compares an expression to a DN to a string, it converts the string to a distinguished name before evaluating the expression. If the system cannot convert the string due to bad syntax, the comparison fails. The DN variables are:

- userDN
- certDN
- certIssuerDN

The system also supports DN suffix comparisons using the **matchDNSuffix** function. For example:

```
matchDNSuffix( certDn, "dc=danastreet,dc=net")
```

Within the parenthesis, the first parameter is the "full" DN and the second is the suffix DN. You can use a or string for each parameter. Note that this first parameter should have more keys than the second (suffix parameter). Otherwise, if they are equal, it is the same as <firstparam> = <secondparam>. If the second parameter has more keys, matchDNsuffix returns false.

System Variables

The below table lists and defines system variables, gives an example for each system variable, and provides a guide as to where you may use system variables.

Variable	Description	Usage	Examples
authMethod	Type of authentication method used to authenticates a user.	role mapping rules, resource policy rules	authMethod = 'ACE Server'
certAttr.<cert-attr>	<p>Attributes from a client-side certificate. Examples of certAttr attributes include:</p> <ul style="list-style-type: none">• C - country• CN - common name• description - description• e-mailAddress - e-mail address• GN - given name• initials - initials• L - locality name• O - organization• OU - organizational unit• SN - surname• serialNumber- serial number• ST - state or province• title - title• UI - unique identifier <p>Use this variable to check that the user's client has a client-side certificate with the value(s) specified.</p>	<ul style="list-style-type: none">• role mapping rules• resource policy rules• SSO parameter fields• LDAP configuration	certAttr.OU = 'Retail Products Group'

Variable	Description	Usage	Examples
certAttr.altName.<Alt-attr>	<p>Subject alternative name value from a client-side certificate where <Alt-attr> may be:</p> <ul style="list-style-type: none">EmailEmailIdEmailDomainDNSregisteredIdipAddressUPNUPNidUPNDomainfascnfascnACfascnSCfascnCNfascnCSfascnICIfascnPIfascnOCfascnOIfascnPOAfascnLRC	<ul style="list-style-type: none">role mapping rulesresource policy rulesSSO parameter fieldsLDAP configuration	<ul style="list-style-type: none">certAttr.altName.ipAddress = 10.10.83.2certAttr.altName.email = "joe@company.com"

Variable	Description	Usage	Examples
certAttr.serialNumber	Client certificate serial number. Note that all characters other than [0-9 a-f A-F] are stripped out of a string before comparison with certAttr.SN. Wildcards are not supported.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields LDAP configuration 	<ul style="list-style-type: none"> certAttr.SerialNumber = userAttr.certSerial certAttr.SerialNumber = "6f:05:45:ab"
certDN	Client certificate subject DN. Wildcards are not permitted.	role mapping rules, resource policy rules	<ul style="list-style-type: none"> ·certDN = userDN (match the certificate subject DN with the LDAP user DN) certDN = userAttr.x509SubjectName certDN = ('cn=John Harding,ou=eng,c=Company' or 'cn=Julia Yount,ou=eng,c=Company')
certDN.<subject-attr>	Any variable from the client certificate subject DN, where subject-attr is the name of the RDN key. Use to test the various subject DN attributes in a standard x.509 certificate.	<ul style="list-style-type: none"> role mapping rules resource policy rules 	<ul style="list-style-type: none"> certDN.OU = 'company' certDN.E = 'joe@company.com' certDN.ST = 'CA'

Variable	Description	Usage	Examples
		<ul style="list-style-type: none"> SSO parameter fields LDAP configuration 	
certDNText	Client certificate user DN stored as a string. Only string comparisons to this value are allowed.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	<ul style="list-style-type: none"> certDNText = 'cn=John Harding,ou=eng,c=Company'
certIssuerDN	Client certificate-issuer subject DN. This variable works like a standard DN attribute such as CertDN. Wildcards are not permitted.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	<ul style="list-style-type: none"> certIssuerDN = 'cn=John Harding,ou=eng,c=Company' certIssuerDN = userAttr.x509Issuer certIssuerDN = ('ou=eng,c=Company' or 'ou=operations,c=Company')
certIssuerDN.<issuer-attr>	Any variable from the client certificate-issuer subject DN, where issuer-attr is the name of the RDN key.	<ul style="list-style-type: none"> role mapping rules resource policy rules 	<ul style="list-style-type: none"> certIssuerDN.OU = 'company' certIssuerDN.ST = 'CA'

Variable	Description	Usage	Examples
		<ul style="list-style-type: none">SSO parameter fields	
certIssuerDNText	Client certificate-issuer subject DN stored as a string. Only string comparisons to this value are allowed.	<ul style="list-style-type: none">role mapping rulesresource policy rulesSSO parameter fields	<ul style="list-style-type: none">certIssuerDNText = 'cn=John Harding,ou=eng,c=Company'
defaultNTDomain	Contains the Domain value set in the authentication server configuration when you use AD/NT authentication.	<ul style="list-style-type: none">role mapping rulesresource policy rulesSSO parameter fields	defaultNTDomain="CORP"
group.<group-name>	User's group membership as provided by the realm authentication or directory server.	<ul style="list-style-type: none">role mapping rulesresource policy rules	<ul style="list-style-type: none">group.preferredPartnergroup.goldPartner or group.silverPartnergroup.employees and time.month = 9Combination examples:

Variable	Description	Usage	Examples
		<ul style="list-style-type: none"> Only those groups evaluated for role mapping rules are available in the detailed rules (conditions) in the resource policies. We recommend that you use the groups variable instead of group.<group-name>, which is supported only for backwards compatibility. 	<ul style="list-style-type: none"> Allow all partners with active status from Monday to Friday but preferred partners Monday through Saturday: ((group.partners and time = (Mon to Fri)) or (group.preferredPartners and time = (Mon to Sat))) and userAttr.partnerStatus = 'active' <hr/> <p> Spaces are not supported, such as, group.sales managers</p> <hr/>
Groups	List of groups as provided by the realm authentication or directory server.	<ul style="list-style-type: none"> role mapping rules 	groups=('sales managers')

Variable	Description	Usage	Examples
	<p> You can enter any characters in the groupname, although wildcard characters are not supported.</p>	<ul style="list-style-type: none"> resource policy rules SSO parameter fields 	
hostCheckerPolicy	Host Checker polices that the client has met.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	<code>hostCheckerPolicy = ('Norton' and 'Sygate')</code> and <code>cacheCleanerStatus = 1</code> <code>hostCheckerPolicy = ('Norton' and 'Sygate')</code>
log inHost	Hostname or IP address that the browser uses to contact the Ivanti service.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields LDAP configuration 	<code>log inHost = 10.10.10.10</code>
log inTime	The time of day at which the user submits his credentials. The time is based on system time.	<ul style="list-style-type: none"> role mapping rules resource policy rules 	<ul style="list-style-type: none"> <code>log inTime = (8:00am)</code> <code>log inTime= (Mon to Fri)</code>

Variable	Description	Usage	Examples
	 <p>When using this variable in an SSO parameter field, the variable returns the UNIX string time.</p>	<ul style="list-style-type: none"> SSO parameter fields 	
log inTime.day	<p>The day of month on which the user submits his credentials, where day is 1-31. The time is based on the system time.</p> <p>You cannot use the TO operator with this variable.</p>	<ul style="list-style-type: none"> role mapping rules resource policy rules 	log inTime.day = 3
log inTime.dayOfWeek	<p>The day of the week on which the user submits his credentials, where dayOfWeek is in the range [0-6] where 0 = Sunday.</p> <p>The system does not support the TO operator with time.dayOfWeek expressions if you use numbers instead of strings. In other words, "log inTime.dayOfWeek = (2 TO 6)" does not work, but "log inTime.dayOfWeek = (mon to fri)" does work.</p>	<ul style="list-style-type: none"> role mapping rules resource policy rules 	<ul style="list-style-type: none"> log inTime.dayOfWeek = (0 OR 6) log inTime.dayOfWeek = (mon TO fri) log inTime.dayOfWeek = (1) log inTime.dayOfWeek = 5
log inTime.dayOfYear	<p>The numeric day of the year on which the user submits his credentials, where dayOfYear can be set to [0-365].</p> <p>You cannot use the TO operator with this variable.</p>	<ul style="list-style-type: none"> role mapping rules resource policy rules 	log inTime.dayOfYear = 100

Variable	Description	Usage	Examples
log inTime.month	The month in which the user submits his credentials, where month can be set to [1-12] where 1 = January. You cannot use the TO operator with this variable.	<ul style="list-style-type: none">• role mapping rules• resource policy rules	log inTime.month >= 4 AND log inTime.month <=9
log inTime.year	The year in which the user submits his credentials, where year can be set to [1900-2999]. You cannot use the TO operator with this variable.	<ul style="list-style-type: none">• role mapping rules• resource policy rules	log inTime.year = 2005
log inURL	URL of the page that the user accessed to sign in. The system gets this value from the Administrator URLs User URLs column on the Authentication > Signing In > Sign-in Policies page of the admin console.	<ul style="list-style-type: none">• role mapping rules• resource policy rules• SSO parameter fields• LDAP configuration	log inURL = */admin
networkIf	The network interface on which the user request is received. Possible values: internal, external	<ul style="list-style-type: none">• role mapping rules• resource policy rules• SSO parameter fields	sourceIp = 192.168.1.0/24 and networkIf = internal

Variable	Description	Usage	Examples
Ntdomain	The NetBIOS NT domain used in NT4 and Active Directory authentication.	<ul style="list-style-type: none"> role mapping rules SSO parameter fields 	ntdomain = jnpr
Ntuser	The NT username used in Active Directory authentication	<ul style="list-style-type: none"> role mapping rules SSO parameter fields 	ntuser = jdoe password password[1]
password[2]	The password entered by the user for the primary authentication server (password and password[1]) or the secondary authentication server (password[2]).	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	password = A1defo2z
Realm	The name of the authentication realm to which the user is signed in.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	<p>Realm = ('GoldPartners' or 'SilverPartners')</p> <hr/> <p> AND condition will always fail as a user is only allowed to sign in to a single realm in a session.</p> <hr/>
Role	List of all the user roles for the session.	<ul style="list-style-type: none"> resource policy rules 	<ul style="list-style-type: none"> Role = ('sales' or 'engineering')

Variable	Description	Usage	Examples
	<p>Role = ('Sales' AND 'Support')</p> <p>In SSO, if you want to send all the roles to back-end applications, use <role sep = ";"> - where sep is the separator string for multiple values. The system supports all separators except " and >.</p>	<ul style="list-style-type: none"> SSO parameter fields 	<ul style="list-style-type: none"> "Role = ('Sales' AND 'Support')
radius.requestAttributes.<req Attrs>	<p>The list of default value are as follows:</p> <ul style="list-style-type: none"> radius.requestAttributes.Calling-Station-Id = <ANY> radius.requestAttributes.NAS-IP-Address = <ANY> radius.requestAttributes.NAS-Identifier = <ANY> radius.requestAttributes.NAS-Port-Type = <ANY> radius.requestAttributes.Called-Station-Id = <ANY> radius.requestAttributes.Aruba-Essid-Name = <ANY> radius.requestAttributes.User-Name = <ANY> 	role mapping rules	radius.requestAttributes.Calling-Station-Id = "00:aa:3f:*

Variable	Description	Usage	Examples
locationGroup	Allows the user to filter the roles based on the location group.	role mapping rules	locationGroup = "bangalore"
eapProtocol.<protocolLayer>	<p>Allows the user to filter the roles based on EAP protocol.</p> <p><protocolLayer> indicates whether the variable matches the inner protocol or outer protocol.</p> <ul style="list-style-type: none"> The values for the outerProtocol variable are EAP-PEAP and EAP-TTLS. The values for the innerProtocol are PAP, CHAP, MS-CHAP, MS-CHAP-V2, EAP-MD5, EAP-TLS, EAP-MSCHAP-V2, EAP-GTC, and EAP-JUAC. 	<ul style="list-style-type: none"> role mapping rules 	eap-protocol.outerProtocol != "EAP-PEAP"
sourceIP	The IP address of the machine on which the user authenticates. You can specify the netmask using the bit number or in the netmask format: '255.255.0.0'. Note that you can evaluate the sourceIP expression against a string variable such as an LDAP attribute.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	<ul style="list-style-type: none"> sourceIP = 192.168.10.20 sourceIP = 192.168.1.0/24 and networkIf internal userAttr.dept = ('eng' or 'it') and sourceIP = 10.11.0.0/16 sourceIP = 192.168.10.0/24 (Class C) <p>is the same as:</p>

Variable	Description	Usage	Examples
			<ul style="list-style-type: none"> sourceIP = 192.168.10.0/255.255.255.0 sourceIP=userAttr.sourceip
Time	The time of day at which the role mapping rule or resource policy rule is evaluated. The time of the day can be in 12-hour or 24-hour format.	<ul style="list-style-type: none"> role mapping rules resource policy rules 	<ul style="list-style-type: none"> time = (09:00 to 17:00) time = (Mon to Fri) time = (9:00am to 5:00pm) <p>Combination examples: Allow executive managers and their assistants access from Monday to Friday: userAttr.employeeType = ('*manager*' or '*assistant*') and group.executiveStaff and time = (Mon to Fri)</p>
time.dayOfWeek	The day of the week on which the role mapping rule or resource policy rule is evaluated, where dayOfWeek is in the range [0-6] where 0 = Sunday.	<ul style="list-style-type: none"> role mapping rules resource policy rules 	<p>log inTime.dayOfWeek = (0 OR 6)</p> <p>log inTime.dayOfWeek = (1 to 5)</p> <p>log inTime.dayOfWeek = 5</p>
time.dayOfYear	The day of the year on which the role mapping rule or resource policy rule is evaluated. Possible values include: 1-365.	<ul style="list-style-type: none"> role mapping rules resource policy rules 	time.dayOfYear = 100

Variable	Description	Usage	Examples
time.month	The month in which the role mapping rule or resource policy rule is evaluated. Possible values include: 1-12	<ul style="list-style-type: none">• role mapping rules• resource policy rules	time.month >= 9 and time.month <= 12 and time.year = 2004 group.employees and time.month = 9
time.year	The year in which the role mapping rule or resource policy rule is evaluated, where year can be set to [1900-2999].	<ul style="list-style-type: none">• role mapping rules• resource policy rules	time.year = 2005

Variable	Description	Usage	Examples
user user@primary_auth_ server_name user@secondary_auth_ server_name	<p>Ivanti username for the user's primary authentication server (user and user@primary_auth_server_name) or secondary authentication server (user@secondary_auth_server_name). Use when authenticating against an Active Directory server, domain and username.</p> <p>primary_auth_server_name is the name of the primary auth server. If there are spaces or special characters in the name, it can be enclosed in curly brackets. For example user@{My Primary Auth Server}</p> <p>secondary_auth_server_name is the name of the secondary auth server. If there are spaces or special characters in the name, it can be enclosed in curly brackets. For example user@{My Secondary Auth Server}</p> <hr/> <p>When including a domain as part of a username, you must include two slashes between the domain and user. For example: user='yourcompany.net\joeuser'.</p>	<ul style="list-style-type: none">• role mapping rules• resource policy rules• SSO parameter fields	<ul style="list-style-type: none">• user = 'steve'• user = 'domain\\steve'

Variable	Description	Usage	Examples
username username@primary_auth_server_name username@secondary_auth_server_name	System username for the user's primary authentication server (username and username@primary_auth_server_name) or secondary authentication server (username@secondary_auth_server_name). If the user is signing in to a certificate authentication server, then the user's Ivanti system username is the same as CertDN.cn. primary_auth_server_name is the name of the primary auth server. If there are spaces or special characters in the name, it can be enclosed in curly brackets. For example user@{My Primary Auth Server} secondary_auth_server_name is the name of the secondary auth server. If there are spaces or special characters in the name, it can be enclosed in curly brackets. For example user@{My Secondary Auth Server}	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	<ul style="list-style-type: none"> username = 'steve' and time = mon username = 'steve' username = 'steve*' username = ('steve' or '*jankowski')
userAgent	The browser's user agent string.	<ul style="list-style-type: none"> role mapping rules resource policy rules 	The browser's user agent string.

Variable	Description	Usage	Examples
		<ul style="list-style-type: none">SSO parameter fields	

Variable	Description	Usage	Examples
userAttr.<auth-attr>	User attributes retrieved from an LDAP or RADIUS authentication or directory server.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	<p>userAttr.building = ('HQ*' or 'MtView[1-3]')</p> <p>userAttr.dept = ('sales' and 'eng')</p> <p>userAttr.dept = ('eng' or 'it' or 'custsupport')</p> <p>userAttr.division = 'sales'</p> <p>userAttr.employeeType != 'contractor'</p> <p>userAttr.salaryGrade > 10</p> <p>userAttr.salesConfirmed >= userAttr.salesQuota</p> <p>Negative examples:</p> <p>userAttr.company != "Acme Inc" or not group.contractors</p> <p>not (user = 'guest' or group.demo)</p> <p>Combination examples:</p> <p>Allow executive managers and their assistants access from Monday to Friday:</p> <p>userAttr.employeeType = ('*manager*' or '*assistant*')</p> <p>and</p> <p>group.executiveStaff and time = (Mon to Fri)</p> <p>Allow all partners with active status from Monday to Friday but preferred partners Monday through Saturday:</p> <p>((group.partners and time = (Mon to Fri)) or</p> <p>(group.preferredPartners and time = (Mon to Sat))) and</p>
			(group.preferredPartners and time = (Mon to Sat))) and

Variable	Description	Usage	Examples
			userAttr.partnerStatus = 'active'
userDN	The user DN from an LDAP server. If the user is authenticated by the LDAP server, then this DN is from the authentication server; otherwise, the DN comes from the realm's Directory/Attribute server. Wildcards are not permitted.	<ul style="list-style-type: none"> role mapping rules resource policy rules 	userDN = 'cn=John Harding,ou=eng,c=Company' userDN = certDN
userDN.<user-attr>	Any variable from the user DN, where user-attr is the name of the RDN key.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	Any variable from the user DN, where user-attr is the name of the RDN key.
userDNText	User DN stored as a string. Only string comparisons to this value are allowed.	<ul style="list-style-type: none"> role mapping rules resource policy rules SSO parameter fields 	userDNText = 'cn=John Harding,ou=eng,c=Company'

Custom Variables and Macros

Custom variables, like system variables, are name-value pair tags that you can use when defining role mapping rules, resource policy rules and SSO parameter fields.

Custom variables are created in the Server Catalog (for example, Authentication > Auth Server > *Name* > Settings) by using a predefined macro on a system variable. Available macros are:

- **REGMATCH** – Matches a regular expression pattern against a string text.
- **APPEND** – Appends a text string to another text string.
- **DAYSDIFF** – Calculates the difference between two dates.

These macros are located under Variable Operators in the Variables tab of the Server Catalog window.

A custom variable name is a dot-separated string. Each component can contain characters from the set [a-z A-Z 0-9 _] but cannot start with a digit [0-9]. Custom variable names are case-insensitive.

Custom variables are referenced as **customVar.<variableName>**. For example, if you create a custom variable with the name **check-prefix**, you reference this custom variable as **customVar.check-prefix**.

append

Syntax	APPEND (attr, TextString) APPEND (attr, attr2)
Description	Append a text string to an attribute or append an attribute to another attribute and store the resulting string in the custom variable.
Options	attr —System variable of type string. TextString —Quoted ASCII string. attr2 —System variable of type string.
Output Fields	Returns a String value. If no match is found, returns an empty string If the system variable is multivalued, the custom variable is also multivalued and uses the same order as the system variable.

Sample Output

```
APPEND (userName, "@sample.net")
```

In this example, the string "@sample.net" is appended to the userName value.

daysdiff

Syntax	DAYSDIFF (attr, timeformat)
Description	Calculates the number of days between the attribute and the current time.
Options	attr —System variable of type string.
	timeformat —Output time format. Valid values are: UTC, TIMET, MMDDYYYY
Output Fields	Returns an Integer value.

Sample Output

DAYSDIFF (certAttr.validUpto, UTC)

In this example, calculate the difference in days between the current time and the value of certAttr.validUpto and express the time in UTC (Coordinated Universal Time).

regmatch

Syntax	REGMATCH (attr, regex, groupingNumber)
Description	Match the regular expression pattern against an attribute and store the result in the custom variable. attr —System variable of type string. regex —Quoted string containing the regular expression to be applied to the attr option. groupingNumber —The group value to assign to the custom variable.
Additional Information	The regular expression supports the Perl Compatible Regular Expressions (PCRE) syntax. A grouping (capture buffer) in the regex pattern can also be used to define a custom variable.
Output Fields	Returns a String value. If no match is found, returns an empty string. If the system variable is multivalued, the custom variable is also multivalued and uses the same order as the system variable.

Sample Output

REGMATCH (mailId, "^(.*)@sample.net\$", 1)

In this example, a mailId of myName@sample.net creates a custom variable with value "myName".

Specifying Fetch Attributes in a Realm

To facilitate the support for various parameterized settings in user roles and resource policies, you have the ability to specify additional fetch attributes. The system stores the fetch attributes when users log in so that you can use them in parameterized role or resource policy definitions.

The system pulls all the attributes that are currently stored in the Sever Catalog for the user's authentication or authorization LDAP server. So, make sure to add the LDAP user attributes that are used in role or resource policy definitions in the LDAP Server Catalog first.

When a user logs in, the system retrieves user attributes that are referenced in the role mapping rules plus all of the additional attributes referenced in the Server Catalog and stores all these values. Note that this should not incur a significant performance overhead because all the user attributes are retrieved in one single LDAP query.

When you substitute variables, such as in IP/Netmasks or hostnames, the values in the session are appropriately converted into the data type that is required by the particular application definition.

Specifying the homeDirectory Attribute for LDAP

You can create a bookmark that automatically maps to a user's LDAP home directory. You can accomplish this using the LDAP attribute homeDirectory. You need to configure a realm that specifies the LDAP server instance as its auth server, and you need to configure role-mapping rules and a bookmark that points to the LDAP homeDirectory attribute.
